3.1. Introduction	19
3.2. Toy examples	19
3.2.1. N queens	19
3.2.2. Cloud balancing	23
3.2.3. Traveling salesman (TSP - Traveling salesman problem)	24
3.2.4. Manners 2009	24
3.3. Real examples	24
3.3.1. Course timetabling (ITC 2007 track 3 - Curriculum course scheduling) 2	24
3.3.2. Machine reassignment (Google ROADEF 2012)	25
3.3.3. Vehicle routing	
3.3.4. Hospital bed planning (PAS - Patient admission scheduling)	26
3.4. Difficult examples	
3.4.1. Exam timetabling (ITC 2007 track 1 - Examination)	28
3.4.2. Employee rostering (INRC 2010 - Nurse rostering)	32
3.4.3. Sport scheduling (TTP - Traveling tournament problem)	34
4. Planner configuration	37
4.1. Overview	37
4.2. Solver configuration	37
4.2.1. Solver configuration by XML file	
4.2.2. Solver configuration by Java API	38

4.3. Model your planning problem	39
4.3.1. Is this class a problem fact or planning entity?	39
4.3.2. Problem fact	
4.3.3. Planning entity and planning variables	41
4.3.4. Planning value and planning value ranges	45
4.3.5. Planning problem and planning solution	54
4.4. Use the Solver	59
4.4.1. The Solver interface	59
4.4.2. Solving a problem	60
4.4.3. Environment mode: Are there bugs in my code?	61
4.4.4. Logging level: What is the Solver doing?	62
5. Score calculation	65
5.1. Score terminology	65
5.1.1. What is a score?	65
5.1.2. Negative and positive constraints	65
5.1.3. Score constraint weighting	65
5.1.4. Score level	66
5.1.5. The Score interface	66
5.2. Choose a Score definition	67
5.2.1. SimpleScore	67
5.2.2. HardAndSoftScore (recommended)	67
5.2.3. Implementing a custom Score	67
5.3. Calculate the Score	68
5.3.1. Score calculation types	68
5.3.2. Simple Java score calculation	68
5.3.3. Incremental Java score calculation	70
5.3.4. Drools score calculation	73
5.4. Score calculation performance tricks	77
5.4.1. Overview	77
5.4.2. Incremental score calculation (with delta's)	77
5.4.3. Caching	78
5.4.4. Unused constraint	78
5.4.5. Build-in hard constraint	79
5.4.6. Other performance tricks	79
5.4.7. Score trap	79
5.4.8. stepLimit benchmark	80

Chapter 1. Planner introduction

1.1. What is Drools Planner?

Drools Planner [http://www.jboss.org/drools/drools-planner] is a lightweight, embeddable planning engine that optimizes planning problems. It solves use cases, such as:

- Employee shift rostering: timetabling nurses, repairmen, ...
- Agenda scheduling: scheduling meetings, appointments, maintenance jobs, advertisements, ...
- Educational timetabling: scheduling lessons, courses, exams, conference presentations, ...
- Vehicle routing: planning vehicles (trucks, trains, boats, airplanes, ...) with freight and/or people
- **Bin packing**: filling containers, trucks, ships and storage warehouses, but also cloud computers nodes, ...
- Job shop scheduling: planning car assembly lines, machine queue planning, workforce task planning, ...
- Cutting stock: minimizing waste while cutting paper, steel, carpet, ...
- Sport scheduling: planning football leagues, baseball leagues, ...
- Financial optimization: investment portfolio optimization, risk spreading, ...

Every organization faces planning problems: provide products and services with a limited set of *constrained* resources (employees, assets, time and money).

Drools Planner helps normal JavaTM programmers solve planning problems efficiently. Under the hood, it combines optimization heuristics and metaheuristics with very efficient score calculation.

Drools Planner, like the rest of Drools, is business-friendly *open source* software under *the Apache Software License 2.0* [http://www.apache.org/licenses/LICENSE-2.0] (*layman's explanation* [http://www.apache.org/foundation/licence-FAQ.html#WhatDoesItMEAN]). It is 100% pure JavaTM and runs on any JVM.

1.2. What is a planning problem?

1.2.1. A planning problem is NP-complete

All the use cases above are *probably NP-complete* [http://en.wikipedia.org/wiki/NP-complete]. In layman's terms, this means:

• It's easy to verify a given solution to a problem in reasonable time.

• There is no silver bullet to find the optimal solution of a problem in reasonable time (*).

Note

(*) At least, none of the smartest computer scientists in the world have found such a silver bullet yet. But if they find one for 1 NP-complete problem, it will work for every NP-complete problem.

In fact, there's a \$ 1,000,000 reward for anyone that proves if *such a silver bullet actually exists or not* [http://en.wikipedia.org/wiki/P_%3D_NP_problem].

The implication of this is pretty dire: solving your problem is probably harder than you anticipated, because the 2 common techniques won't suffice:

- A brute force algorithm (even a smarter variant) will take too long.
- A quick algorithm, for example in bin packing, *putting in the largest items first*, will return a solution that is usually far from optimal.

By using advanced optimization algorithms, **Planner does find a good solution in reasonable time for such planning problems.**

1.2.2. A planning problem has (hard and soft) constraints

Usually, a planning problem has at least 2 levels of constraints:

- A (negative) hard constraint must not be broken. For example: 1 teacher can not teach 2 different lessons at the same time.
- A (negative) soft constraint should not be broken if it can be avoided. For example: Teacher A does not like to teach on Friday afternoon.

Some problems have positive constraints too:

• A positive soft constraint (or reward) should be fulfilled if possible. For example: Teacher B likes to teach on Monday morning.

Some toy problems (such as N Queens) only have hard constraints. Some problems have 3 or more levels of constraints, for example hard, medium and soft constraints.

These constraints define the *score calculation* (AKA *fitness function*) of a planning problem. Each solution of a planning problem can be graded with a score. With Planner, score constraints are written in an Object Orientated language, such as Java code or Drools rules. Such code is easy, flexible and scalable.

1.2.3. A planning problem has a huge search space

A planning problem has a number of *solutions*. There are several categories of solutions:

- A *possible solution* is any solution, whether or not it breaks any number of constraints. Planning problems tend to have a incredibly large number of possible solutions. Many of those solutions are worthless.
- A *feasible solution* is a solution that does not break any (negative) hard constraints. The number of feasible solutions tends to be relative to the number of possible solutions. Sometimes there are no feasible solutions. Every feasible solution is a possible solution.
- An *optimal solution* is a solution with the highest score. Planning problems tend to have 1 or a few optimal solutions. There is always at least 1 optimal solution, even in the case that there are no feasible solutions and the optimal solution isn't feasible.
- The *best solution found* is the solution with the highest score found by an implementation in a given amount of time. The best solution found is likely to be feasible and, given enough time, it's an optimal solution.

Counterintuitively, the number of possible solutions is huge (if calculated correctly), even with a small dataset. As you can see in the examples, most instances have a lot more possible solutions than the minimal number of atoms in the known universe (10^80). Because there is no silver bullet to find the optimal solution, any implementation is forced to evaluate at least a subset of all those possible solutions.

Drools Planner supports several optimization algorithms to efficiently wade through that incredibly large number of possible solutions. Depending on the use case, some optimization algorithms perform better than others, but it's impossible to tell in advance. **With Planner, it is easy to switch the optimization algorithm**, by changing the solver configuration in a few lines of XML or code.

1.3. Status of Drools Planner

Drools Planner API production The is almost stable but is ready. backward incompatible changes occur. With the recipe called can UpgradeFromPreviousVersionRecipe.txt [https://github.com/droolsjbpm/drools-planner/blob/ master/drools-planner-distribution/src/main/assembly/filtered-resources/

UpgradeFromPreviousVersionRecipe.txt] you can easily upgrade to a newer version and quickly deal with any backwards incompatible changes. That recipe file is included in every release.

1.4. Download and run the examples

1.4.1. Get the release zip and run the examples

To try it now:

- Download a release zip of Drools Planner from *the Drools download site* [http://www.jboss.org/ drools/downloads.html].
- Unzip it.

• Open the directory examples and run the script.

Linux or Mac:

\$ cd examples \$./runExamples.sh

Windows:

```
$ cd examples
```

```
$ runExamples.bat
```

The Examples GUI application will open. Just pick an example:

\$	Drools Planner examples						
Which example do you want to see?							
Toy examples	Real examples	Difficult examples					
N queens	Course timetabling	Exam timetabling					
		•					
Cloud balancing	Machine reassignment	Employee rostering					
Traveling salesman	Vehicle routing	Sport scheduling					
Manners 2009	Hospital bed planning						
Description							
		•					

Note

Planner itself has no GUI dependencies. It runs just as well on a server or a mobile JVM as on the desktop.

1.4.2. Run the examples in an IDE (IntelliJ, Eclipse, NetBeans)

To run the examples in your favorite IDE, first configure your IDE:

- In IntelliJ and NetBeans, just open the file examples/sources/pom.xml as a new project, the maven integration will take care of the rest.
- In Eclipse, open a new project for the directory examples/sources.
 - Add all the jars to the classpath from the directory binaries and the directory examples/ binaries, except for the file examples/binaries/drools-planner-examples-*.jar.
 - Add the Java source directory src/main/java and the Java resources directory src/main/ resources.

Next, create a run configuration:

- Main class: org.drools.planner.examples.app.DroolsPlannerExamplesApp
- VM parameters (optional): -Xmx512M -server
- Working directory: examples (this is the directory that contains the directory data)

1.4.3. Use it with maven, gradle, ivy, buildr or ANT

The Drools Planner jars are available on *the central maven repository* [http://search.maven.org/ #search|ga|1|org.drools.planner] (and *the JBoss maven repository* [https://repository.jboss.org/ nexus/index.html#nexus-search;gav~org.drools.planner~~~~]).

If you use maven, just add a dependency to drools-planner-core in your project's pom.xml:

```
<dependency>
<groupId>org.drools.planner</groupId>
<artifactId>drools-planner-core</artifactId>
<version>5.x</version>
</dependency>
```

This is similar for gradle, ivy and buildr.

If you're still using ant (without ivy), copy all the jars from the download zip's binaries directory and manually verify that your classpath doesn't contain duplicate jars.

1.4.4. Build it from source

You can also easily build it from source yourself.

Set up Git [http://help.github.com/set-up-git-redirect] and clone drools-planner from GitHub (or alternatively, download *the zipball* [https://github.com/droolsjbpm/drools-planner/zipball/master]):

\$ git clone git@github.com:droolsjbpm/drools-planner.git drools-planner ...

Then do a *Maven* 3 [http://maven.apache.org/] build:

```
$ cd drools-planner
$ mvn -DskipTests clean install
...
```

After that, you can run any example directly from the command line, just run this command and pick an example:

```
$ cd drools-planner-examples
$ mvn exec:exec
...
```

1.5. Questions, issues and blog

Your questions and comments are welcome on *the user mailing list* [http://www.jboss.org/ drools/lists.html]. Start the subject of your mail with [planner]. You can read/ write to the user mailing list without littering your mailbox through *this web forum* [http://drools.46999.n3.nabble.com/Drools-User-forum-f47000.html] or *this newsgroup* [nntp:// news.gmane.org/gmane.comp.java.drools.user].

Feel free to report an issue (such as a bug, improvement or a new feature request) for the Drools Planner code or for this manual to *the drools issue tracker* [https://jira.jboss.org/jira/browse/JBRULES]. Select the component drools-planner.

Pull requests (and patches) are very welcome and get priority treatment! Include the pull request link to a JIRA issue and optionally send a mail to the dev mailing list to get the issue fixed fast. By open sourcing your improvements, you 'll benefit from our peer review and from our improvements made upon your improvements.

Check *our blog* [http://blog.athico.com/search/label/planner], Google+(*Drools Planner* [https://plus.google.com/112724449845406009021], *Geoffrey De Smet* [https:// plus.google.com/112811208792575157490]) and twitter (*Geoffrey De Smet* [http://twitter.com/ geoffreydesmet]) for news and articles. If Drools Planner helps you solve your problem, don't forget to blog or tweet about it!

Chapter 2. Quick start

2.1. Cloud balancing tutorial

2.1.1. Problem statement

Assign each process to a computer.

Hard constraints:

• Every computer should be able to handle the sum of each of the minimal hardware requirements (CPR, RAM, network bandwidth) of all its processes.

Soft constraints:

• Each computer that has one or more processes assigned, has a fixed maintenance cost. Minimize the total cost.

This is a form of bin packing. Here's a simplified example where we assign 4 processes to 2 computers:

2.1.2. Domain model diagram

The domain model is pretty simple:

- Computer: represents a computer with a capacity and cost.
- Process: represents a process with a demand. Needs to be assigned to a Computer.
- CloudBalance: represents a problem. Contains every Computer and Process.

Cloud balance class diagram

planning entity

2.1.3. Main method

Download and configure the examples in your favorite IDE. Run org.drools.planner.examples.cloudbalancing.app.CloudBalancingHelloWorld. By default, it is configured to run for 120 seconds.

Example 2.1. CloudBalancingHelloWorld.java

```
public class CloudBalancingHelloWorld {
```

```
public static void main(String[] args) {
        // Build the Solver
        SolverFactory solverFactory = new XmlSolverFactory(
                           "/org/drools/planner/examples/cloudbalancing/solver/
cloudBalancingSolverConfig.xml");
       Solver solver = solverFactory.buildSolver();
        // Load a problem with 400 computer and 1200 processes
       CloudBalance unsolvedCloudBalance = new CloudBalancingGenerator().createCloudBalance(4
        // Solve the problem
       solver.setPlanningProblem(unsolvedCloudBalance);
        solver.solve();
     CloudBalance solvedCloudBalance = (CloudBalance) solver.getBestSolution();
        // Display the result
         System.out.println("\nSolved cloudBalance with 400 computers and 1200
processes:\n"
                + toDisplayString(solvedCloudBalance));
    }
    . . .
}
```

This code above basically does this:

- Build the Solver.
- Load the problem. CloudBalancingGenerator generates a random problem: you'll replace this with a class that loads a real problem, for example from a database.
- · Solve the problem.
- Display the result.

The only non-obvious part is building the solver. Let's examine that.

2.1.4. Solver configuration

Take a look at the solver configuration:

Example 2.2. cloudBalancingSolverConfig.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<solver>
  <!--<environmentMode>DEBUG</environmentMode>-->
  <!-- Domain model configuration -->
```

```
<solutionClass>org.drools.planner.examples.cloudbalancing.domain.CloudBalance
               solutionClass>
<planningEntityClass>org.drools.planner.examples.cloudbalancing.domain.CloudProcess
               planningEntityClass>
                 <!-- Score configuration -->
                 <scoreDirectorFactory>
                   <scoreDefinitionType>HARD_AND_SOFT</scoreDefinitionType>
solver.score.CloudBalancingSimpleScoreCalculator</
               simpleScoreCalculatorClass>
                             <!--<scoreDrl>/org/drools/planner/examples/cloudbalancing/solver/
               cloudBalancingScoreRules.drl</scoreDrl>-->
                 </scoreDirectorFactory>
                 <!-- Optimization algorithms configuration -->
                 <termination>
                   <maximumSecondsSpend>120</maximumSecondsSpend>
                 </termination>
                 <constructionHeuristic>
                   <constructionHeuristicType>FIRST_FIT_DECREASING</constructionHeuristicType>
               <constructionHeuristicPickEarlyType>FIRST_LAST_STEP_SCORE_EQUAL_OR_IMPROVING
               constructionHeuristicPickEarlyType>
                 </constructionHeuristic>
                 <localSearch>
                   <selector>
                     <selector>
        <moveFactoryClass>org.drools.planner.core.move.generic.GenericChangeMoveFactory</
               moveFactoryClass>
                     </selector>
                     <selector>
             kmoveFactoryClass>org.drools.planner.core.move.generic.GenericSwapMoveFactory
               moveFactoryClass>
                     </selector>
                   </selector>
                   <acceptor>
                     <planningEntityTabuSize>7</planningEntityTabuSize>
                   </acceptor>
                   <forager>
                     <minimalAcceptedSelection>1000</minimalAcceptedSelection>
                   </forager>
                 </localSearch>
               </solver>
```

This consists out of 3 parts:

- Domain model configuration: What can Planner change?
- · Score configuration: What should Planner optimize?
- **Optimization algorithms configuration**: How should Planner optimize it? Don't worry about this for now: this is a good default configuration that works on most planning problems.

Let's examine the domain model and the score configuration.

2.1.5. Domain model implementation

The class *computer* is a POJO (Plain Old Java Object), nothing special. Usually, you'll have more of these kind of classes.

Example 2.3. CloudComputer.java

```
public class CloudComputer ... {
    private int cpuPower;
    private int memory;
    private int networkBandwidth;
    private int cost;
    ... // getters
}
```

The class Process is a little bit special. We need to tell Planner that it can change the field computer, so we annotate the class with @PlanningEntity and the getter getComputer with @PlanningVariable:

Example 2.4. CloudProcess.java

```
return computer;
   }
   public void setComputer(CloudComputer computer) {
       computer = computer;
   }
   // *********
                            // Complex methods
   // ******
   public CloudProcess clone() {
       CloudProcess clone = new CloudProcess();
       clone.id = id;
       clone.requiredCpuPower = requiredCpuPower;
       clone.requiredMemory = requiredMemory;
       clone.requiredNetworkBandwidth = requiredNetworkBandwidth;
       clone.computer = computer;
       return clone;
   }
   . . .
}
```

The values that Planner can chose from for the field computer, are retrieved from a method on the Solution implementation: CloudBalance.getComputerList().

The class CloudBalance implements the Solution interface. It holds a list of all computers and processes. It has a property score which is the score of that Solution instance in it's current state:

Example 2.5. CloudBalance.java

```
public class CloudBalance ... implements Solution<HardAndSoftScore> {
    private List<CloudComputer> computerList;
    private List<CloudProcess> processList;
    private HardAndSoftScore score;
    public List<CloudComputer> getComputerList() {
        return computerList;
    }
    @PlanningEntityCollectionProperty
```

```
public List<CloudProcess> getProcessList() {
       return processList;
   }
    . . .
   public HardAndSoftScore getScore() {
       return score;
   }
   public void setScore(HardAndSoftScore score) {
       this.score = score;
   }
   // *********
                           // Complex methods
                                  // **********
   public Collection<? extends Object> getProblemFacts() {
       List<Object> facts = new ArrayList<Object>();
       facts.addAll(computerList);
        \ensuremath{{//}} Do not add the planning entity's (processList) because that will
be done automatically
      return facts;
   }
   /**
    * Clone will only deep copy the {@link #processList}.
    */
   public CloudBalance cloneSolution() {
       CloudBalance clone = new CloudBalance();
       clone.id = id;
       clone.computerList = computerList;
       List<CloudProcess> clonedProcessList = new ArrayList<CloudProcess>(
               processList.size());
       for (CloudProcess process : processList) {
           CloudProcess clonedProcess = process.clone();
           clonedProcessList.add(clonedProcess);
       }
       clone.processList = clonedProcessList;
       clone.score = score;
       return clone;
   }
   • • •
}
```

The method getProblemFacts() is only needed for score calculation with Drools. It's not needed with the other score calculation types.

The method clone() is required. Planner uses it to make a clone of the best solution in encounters during searching.

2.1.6. Score configuration

Planner will search for the solution with the highest score. We're using a HardAndSoftScore, which means Planner will look for the solution with no hard constraints broken (hardware requirements) and as little as possible soft constraints broken (maintenance cost).

There are several ways to implement the score function:

- Simple Java
- Incremental Java
- Drools

Let's look at 2 of those:

2.1.6.1. Simple Java score configuration

One way to define a score function is to implement the interface SimpleScoreCalculator in plain Java.

```
<scoreDirectorFactory>
  <scoreDefinitionType>HARD_AND_SOFT</scoreDefinitionType>
```

solver.score.CloudBalancingSimpleScoreCalculator</

```
simpleScoreCalculatorClass>
  </scoreDirectorFactory>
```

Just implement the method calculateScore(Solution) to return a DefaultHardAndSoftScore instance.

Example 2.6. CloudBalance.java

```
public class CloudBalancingSimpleScoreCalculator implements SimpleScoreCalculator<CloudBalance:
public Score calculateScore(CloudBalance cloudBalance) {
    Map<CloudComputer, Integer> cpuPowerUsageMap = new HashMap<>();
    ...
    for (CloudComputer computer : cloudBalance.getComputerList()) {
        cpuPowerUsageMap.put(computer, 0);
        ...
    }
```

```
Set<CloudComputer> usedComputerSet = new HashSet<>();
           visitProcessList(cpuPowerUsageMap, ...,
                               usedComputerSet, cloudBalance.getProcessList());
            int hardScore = sumHardScore(cpuPowerUsageMap, ...);
            int softScore = sumSoftScore(usedComputerSet);
           return DefaultHardAndSoftScore.valueOf(hardScore, softScore);
  }
  private void visitProcessList(Map<CloudComputer, Integer> cpuPowerUsageMap, ...
                 Set<CloudComputer> usedComputerSet, List<CloudProcess> processList) {
            // We loop through the processList only once for performance
            for (CloudProcess process : processList) {
                     CloudComputer computer = process.getComputer();
                     if (computer != null) {
                                int cpuPowerUsage = cpuPowerUsageMap.get(computer) + process.getRequiredCpuPowerUsageMap.get(computer) + process.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getRequiredCpuPowerUsageMap.getR
                               cpuPowerUsageMap.put(computer, cpuPowerUsage);
                                . . .
                               usedComputerSet.add(computer);
                      }
            }
  }
private int sumHardScore(Map<CloudComputer, Integer> cpuPowerUsageMap, ...) {
            int hardScore = 0;
            for (Map.Entry<CloudComputer, Integer> usageEntry : cpuPowerUsageMap.entrySet()) {
                     CloudComputer computer = usageEntry.getKey();
              int cpuPowerAvailable = computer.getCpuPower() - usageEntry.getValue();
                     if (cpuPowerAvailable < 0) {</pre>
                               hardScore += cpuPowerAvailable;
                      }
            }
            . . .
           return hardScore;
  }
 private int sumSoftScore(Set<CloudComputer> usedComputerSet) {
            int softScore = 0;
            for (CloudComputer usedComputer : usedComputerSet) {
                      softScore -= usedComputer.getCost();
            }
           return softScore;
  }
```

}

Despite that the code above is optimized with Maps to only go through the processList once, it is still slow because it doesn't do incremental score calculation. To fix that, either use an incremental Java score function or a Drools score function.

2.1.6.2. Drools score configuration

To use Drools as a score function, simply add a scoreDrl resource in the classpath:

```
<scoreDirectorFactory>
   <scoreDefinitionType>HARD_AND_SOFT</scoreDefinitionType>
        <scoreDrl>/org/drools/planner/examples/cloudbalancing/solver/
cloudBalancingScoreRules.drl</scoreDrl>
   </scoreDirectorFactory>
```

First, we want to make sure that all computers have enough CPU, RAM and network bandwidth to support all their processes, so we make those hard constraints:

Example 2.7. cloudBalancingScoreRules.drl - hard constraints

<pre>import org.drools.planner.examples.cloudbalancing.domain.CloudBalance;</pre>
<pre>import org.drools.planner.examples.cloudbalancing.domain.CloudComputer;</pre>
<pre>import org.drools.planner.examples.cloudbalancing.domain.CloudProcess;</pre>
global HardAndSoftScoreHolder scoreHolder;
// ####################################
// Hard constraints
// ************************************
rule "requiredCpuPowerTotal"
when
<pre>\$computer : CloudComputer(\$cpuPower : cpuPower)</pre>
<pre>\$requiredCpuPowerTotal : Number(intValue > \$cpuPower) from accumulate(</pre>
CloudProcess(
computer == \$computer,
<pre>\$requiredCpuPower : requiredCpuPower),</pre>
<pre>sum(\$requiredCpuPower)</pre>
)
then
insertLogical(new IntConstraintOccurrence("requiredCpuPowerTotal",
ConstraintType.NEGATIVE_HARD,
<pre>\$requiredCpuPowerTotal.intValue() - \$cpuPower,</pre>
<pre>\$computer));</pre>
end

```
rule "requiredMemoryTotal"
   . . .
end
rule "requiredNetworkBandwidthTotal"
end
// Calculate hard score
// *****
// Accumulate hard constraints
rule "hardConstraintsBroken"
      salience -1 // Do the other rules first (optional, for performance)
   when
      $hardTotal : Number() from accumulate(
      IntConstraintOccurrence(constraintType == ConstraintType.NEGATIVE_HARD,
$weight : weight),
         sum($weight)
      )
   then
      scoreHolder.setHardConstraintsBroken($hardTotal.intValue());
end
```

Next, if those constraints are met, we want to minimize the maintenance cost, so we add that as a soft constraint:

Example 2.8. cloudBalancingScoreRules.drl - soft constraints

2.1.7. Beyond this tutorial

Now that this simple example works, you can go further. Try this:

- Each Process belongs to a Service. A computer can crash, so processes running the same service should be assigned to different Computers.
- Each Computer is located in a Building. A building can burn down, so processes of the same services should be assigned to computers in different buildings.

Chapter 3. Use cases and examples

3.1. Introduction

Drools Planner has several examples. In this manual we explain Drools Planner mainly using the n queens example. So it's advisable to read at least the section about that example. For advanced users, the following examples are recommended: curriculum course and nurse rostering.

You can find the source code of all these examples in the distribution zip under examples/sources and also in git under drools-planner/drools-planner-examples.

3.2. Toy examples

3.2.1. N queens

3.2.1.1. Problem statement

The *n* queens puzzle is a puzzle with the following constraints:

- Use a chessboard of *n* columns and *n* rows.
- Place *n* queens on the chessboard.
- No 2 queens can attack each other. Note that a queen can attack any other queen on the same horizontal, vertical or diagonal line.

The most common n queens puzzle is the 8 queens puzzle, with n = 8. We 'll explain Drools Planner using the 4 queens puzzle as the primary example.

A proposed solution could be:

Figure 3.1. A wrong solution for the 4 queens puzzle

The above solution is wrong because queens A1 and B0 can attack each other (as can queens B0 and D0). Removing queen B0 would respect the "no 2 queens can attack each other" constraint, but would break the "place n queens" constraint.

3.2.1.2. Solution(s)

Below is a correct solution:

Figure 3.2. A correct solution for the 4 queens puzzle

All the constraints have been met, so the solution is correct. Note that most n queens puzzles have multiple correct solutions. We 'll focus on finding a single correct solution for a given n, not on finding the number of possible correct solutions for a given n.

3.2.1.3. Screenshot

Here is a screenshot of the example:

				[5]		
		[2]				
			[4]			
						[7]
[0]						
	11 [1]					
					[6]	

Figure 3.3. Screenshot of the n queens example

3.2.1.4. Problem size

These numbers might give you some insight on the size of this problem.

Table 3.1. NQueens problem size

# queens (n)	solutions (each	# feasible solutions (= optimal in this use case)	-	# optimal <i>out of</i> # possible
4	256	2	2	1 out of 128
8	16777216	64	64	1 out of 262144
16	184467440737095	551467762512	14772512	1 out of 1248720872503

# queens (n)	solutions (each queen its own	solutions (=	# optimal solutions	# optimal <i>out of</i> # possible
32	1.4615016373309 +48	0 2 91820368483e	?	?
64	3.9402006196394 +115	4 7 92122790401e	?	?
n	n ^ n	?	# feasible solutions	?

The Drools Planner implementation has not been optimized because it functions as a beginner example. Nevertheless, it can easily handle 64 queens.

3.2.1.5. Domain model

Use a good domain model: it will be easier to understand and solve your planning problem with Drools Planner. This is the domain model for the n queens example:

```
public class Column {
    private int index;
    // ... getters and setters
}
```

```
public class Row {
    private int index;
    // ... getters and setters
}
```

```
public class Queen {
    private Column column;
    private Row row;
    public int getAscendingDiagonalIndex() {...}
    public int getDescendingDiagonalIndex() {...}
    // ... getters and setters
```

}

```
public class NQueens implements Solution<SimpleScore> {
    private int n;
    private List<Column> columnList;
    private List<Row> rowList;
    private List<Queen> queenList;
    private SimpleScore score;
    // ... getters and setters
}
```

A Queen instance has a Column (for example: 0 is column A, 1 is column B, ...) and a Row (its row, for example: 0 is row 0, 1 is row 1, ...). Based on the column and the row, the ascending diagonal line as well as the descending diagonal line can be calculated. The column and row indexes start from the upper left corner of the chessboard.

A solution	Queen	columnIndex	rowIndex		ب descendingDia (columnIndex - rowIndex)
A B	đр	0	1	1 (**)	-1
o 🕅	8888	1	0 (*)	1 (**)	1
1 99982		2	2	4	0
2		3	0 (*)	3	3

Table 3.2. A solution for the 4 queens puzzle shown in the domain model

When 2 queens share the same column, row or diagonal line, such as (*) and (**), they can attack each other.

A single NQueens instance contains a list of all Queen instances. It is the Solution implementation which will be supplied to, solved by and retrieved from the Solver. Notice that in the 4 queens example, NQueens's getN() method will always return 4.

3.2.2. Cloud balancing

This example is explained in a tutorial.

3.2.3. Traveling salesman (TSP - Traveling salesman problem)

3.2.3.1. Problem statement

Given a list of cities, find the shortest tour for a salesman that visits each city exactly once. See the wikipedia definition of the traveling Salesman Problem. [http://en.wikipedia.org/wiki/ Travelling_salesman_problem]

It is *one of the most intensively studied problems* [http://www.tsp.gatech.edu/] in computational mathematics. Yet, in the real world, it's often only part of a planning problem, along with other constraints, such as employee shift time constraints.

3.2.4. Manners 2009

3.2.4.1. Problem statement

In Manners 2009, miss Manners is throwing a party again.

- This time she invited 144 guests and prepared 12 round tables with 12 seats each.
- Every guest should sit next to someone (left and right) of the opposite gender.
- And that neighbour should have at least one hobby in common with the guest.
- Also, this time there should be 2 politicians, 2 doctors, 2 socialites, 2 sports stars, 2 teachers and 2 programmers at each table.
- And the 2 politicians, 2 doctors, 2 sports stars and 2 programmers shouldn't be the same kind.

Drools Expert also has the normal miss Manners examples (which is much smaller) and employs a brute force heuristic to solve it. Drools Planner's implementation employs far more scalable heuristics while still using Drools Expert to calculate the score..

3.3. Real examples

3.3.1. Course timetabling (ITC 2007 track 3 - Curriculum course scheduling)

3.3.1.1. Problem statement

Schedule each lecture into a timeslot and into a room.

The problem is defined by *the International Timetabling Competition 2007 track 3* [http:// www.cs.qub.ac.uk/itc2007/curriculmcourse/course_curriculm_index.htm].

3.3.2. Machine reassignment (Google ROADEF 2012)

3.3.2.1. Problem statement

Assign each process to a machine. All processes already have an original (unoptimized) assignment. Each process requires an amount of each resource (such as CPU, RAM, ...). This is more complex version of the Cloud balancing example.

The problem is defined by *the Google ROADEF/EURO Challenge 2012* [http:// challenge.roadef.org/2012/en/].

Hard constraints:

- Maximum capacity: The maximum capacity for each resource for each machine must not be exceeded.
- Conflict: Processes of the same service must run on distinct machines.
- Spread: Processes of the same service must be spread across locations.
- Dependency: The processes of a service depending on another service must run in the neighborhood of a process of the other service.
- Transient usage: Some resources are transient and count towards the maximum capacity of both the original machine as the newly assigned machine.

Soft constraints:

- Load: The safety capacity for each resource for each machine should not be exceeded.
- Balance: Leave room for future assignments by balancing the available resources on each machine.
- Process move cost: A process has a move cost.
- Service move cost: A service has a move cost.
- Machine move cost: Moving a process from machine A to machine B has another A-B specific move cost.

3.3.2.2. Problem size

```
model_a1_1: 2 resources, 1 neighborhoods, 4 locations, 4 machines, 79 services,
100 processes and 1 balancePenalties with flooredPossibleSolutionSize (10^60).
model_a1_2: 4 resources, 2 neighborhoods, 4 locations, 100 machines, 980
services, 1000 processes and 0 balancePenalties with flooredPossibleSolutionSize
(10^2000).
```

```
model_a1_3: 3 resources, 5 neighborhoods, 25 locations, 100 machines, 216
services, 1000 processes and 0 balancePenalties with flooredPossibleSolutionSize
 (10^{2000}).
model_a1_4: 3 resources, 50 neighborhoods, 50 locations, 50 machines, 142
services, 1000 processes and 1 balancePenalties with flooredPossibleSolutionSize
(10^1698).
model_a1_5: 4 resources, 2 neighborhoods, 4 locations, 12 machines, 981
services, 1000 processes and 1 balancePenalties with flooredPossibleSolutionSize
(10^1079).
model_a2_1: 3 resources, 1 neighborhoods, 1 locations, 100 machines, 1000
services, 1000 processes and 0 balancePenalties with flooredPossibleSolutionSize
(10^{2000}).
model_a2_2: 12 resources, 5 neighborhoods, 25 locations, 100 machines, 170
services, 1000 processes and 0 balancePenalties with flooredPossibleSolutionSize
 (10^{2000}).
model_a2_3: 12 resources, 5 neighborhoods, 25 locations, 100 machines, 129
services, 1000 processes and 0 balancePenalties with flooredPossibleSolutionSize
(10^2000).
model_a2_4: 12 resources, 5 neighborhoods, 25 locations, 50 machines, 180
services, 1000 processes and 1 balancePenalties with flooredPossibleSolutionSize
(10^1698).
model_a2_5: 12 resources, 5 neighborhoods, 25 locations, 50 machines, 153
services, 1000 processes and 0 balancePenalties with flooredPossibleSolutionSize
 (10^1698).
```

3.3.3. Vehicle routing

3.3.3.1. Problem statement

Using a fleet of vehicles, pick up the objects of each customer and bring them to the depot. Each vehicle can service multiple customers, but it has a limited capacity.

The capacitated vehicle routing problem (CRVP) is defined by *the VRP web* [http://neo.lcc.uma.es/ radi-aeb/WebVRP/].

3.3.4. Hospital bed planning (PAS - Patient admission scheduling)

3.3.4.1. Problem statement

Assign each patient (that will come to the hospital) into a bed for each night that the patient will stay in the hospital. Each bed belongs to a room and each room belongs to a department. The arrival and departure dates of the patients is fixed: only a bed needs to be assigned for each night.

There are a couple of hard constraints:

• 2 patients shouldn't be assigned to the same bed in the same night.

- A room can have a gender limitation: only females, only males, the same gender in the same night or no gender limitation at all.
- A department can have a minimum or maximum age.
- A patient can require a room with specific equipment(s).

And of course, there are also some soft constraints:

- A patient can prefer a maximum room size, for example if he/she want a single room.
- A patient is best assigned to a department that specializes in his/her problem.
- A patient is best assigned to a room that specializes in his/her problem.
- A patient can prefer a room with specific equipment(s).

The problem is defined on *this webpage* [http://allserv.kahosl.be/~peter/pas/] and the test data comes from real world hospitals.

Patient admission schedule

Assign each patient a hospital bed.

3.4. Difficult examples

3.4.1. Exam timetabling (ITC 2007 track 1 - Examination)

3.4.1.1. Problem statement

Schedule each exam into a period and into a room. Multiple exams can share the same room during the same period.

There are a number of hard constraints that cannot be broken:

- Exam conflict: 2 exams that share students should not occur in the same period.
- Room capacity: A room's seating capacity should suffice at all times.
- Period duration: A period's duration should suffice for all of its exams.
- · Period related hard constraints should be fulfilled:
 - Coincidence: 2 exams should use the same period (but possibly another room).
 - Exclusion: 2 exams should not use the same period.
 - After: 1 exam should occur in a period after another exam's period.
- Room related hard constraints should be fulfilled:
 - Exclusive: 1 exam should not have to share its room with any other exam.

There are also a number of soft constraints that should be minimized (each of which has parametrized penalty's):

- 2 exams in a row.
- 2 exams in a day.
- Period spread: 2 exams that share students should be a number of periods apart.
- Mixed durations: 2 exams that share a room should not have different durations.
- Front load: Large exams should be scheduled earlier in the schedule.
- Period penalty: Some periods have a penalty when used.
- Room penalty: Some rooms have a penalty when used.

It uses large test data sets of real-life universities.
The problem is defined by *the International Timetabling Competition 2007 track 1* [http:// www.cs.qub.ac.uk/itc2007/examtrack/exam_track_index.htm].

3.4.1.2. Problem size

These numbers might give you some insight on the size of this problem.

Table 3.3. Examination problem size

Set	# students	# exams/ topics	# periods	# rooms	# possible solutions	# feasible solutions	# optimal solutions
exam_com	p <u>7</u> 8881	607	54	7	10^1564	?	1?
exam_com	p <u>1</u> 284824	870	40	49	10^2864	?	1?
exam_com	p <u>16865</u>	934	36	48	10^3023	?	1?
exam_com	p <u>4\$21</u> 4	273	21	1	10^360	?	1?
exam_com	p <u>8</u> 36495	1018	42	3	10^2138	?	1?
exam_com	p <u>7_3@9</u> 6	242	16	8	10^509	?	1?

Set	# students		# periods	# rooms	# possible solutions	# feasible solutions	-
exam_com	p <u>1</u> 37975	1096	80	28	10^3671	?	1?
exam_com	p7_ 3688 8	598	80	8	10^1678	?	1?
?	S	t	р	r	(p * r) ^ e	?	1?

Geoffrey De Smet (the Drools Planner lead) finished 4th in the International Timetabling Competition 2007's examination track with a very early version of Drools Planner. Many improvements have been made since then.

3.4.1.3. Domain model

Below you can see the main examination domain classes:

Figure 3.4. Examination domain class diagram

Notice that we've split up the exam concept into an Exam class and a Topic class. The Exam instances change during solving (this is the planning entity class), when they get another period or room property. The Topic, Period and Room instances never change during solving (these are problem facts, just like some other classes).

3.4.2. Employee rostering (INRC 2010 - Nurse rostering)

3.4.2.1. Problem statement

For each shift, assign a nurse to work that shift.

The problem is defined by *the International Nurse Rostering Competition 2010* [http:// www.kuleuven-kortrijk.be/nrpcompetition].

No hard constraint broken => solution is feasible

Employee shift rostering Soft constraints

There are many more soft constraints...

3.4.3. Sport scheduling (TTP - Traveling tournament problem)

3.4.3.1. Problem statement

Schedule matches between *n* teams with the following hard constraints:

- Each team plays twice against every other team: once home and once away.
- Each team has exactly 1 match on each timeslot.
- No team must have more than 3 consecutive home or 3 consecutive away matches.
- No repeaters: no 2 consecutive matches of the same 2 opposing teams.

and the following soft constraint:

• Minimize the total distance traveled by all teams.

The problem is defined on *Michael Trick's website (which contains several world records too)* [http://mat.gsia.cmu.edu/TOURN/].

3.4.3.2. Simple and smart implementation

There are 2 implementations (simple and smart) to demonstrate the importance of some performance tips. The DroolsPlannerExamplesApp always runs the smart implementation, but with these commands you can compare the 2 implementations yourself:

\$ mvn	exec:exec	-
Dexec.mainClass="org.drools.planner.	.examples.travelingtournament.app	.simple.SimpleTravelingTour
\$ mvn	exec:exec	-
Dexec.mainClass="org.drools.planner.	.examples.travelingtournament.app	.smart.SmartTravelingTourna

The smart implementation performs and scales exponentially better than the simple implementation.

3.4.3.3. Problem size

These numbers might give you some insight on the size of this problem.

# teams	# days	# matches	# possible solutions (simple)	solutions		# optimal solutions
4	6	12	2176782336	<= 518400	?	1?
6	10	30	1000000000	0 000 0000000 4778472583	0 0 00000000 9872000000	1?
8	14	56	1.524649437 +64	7 <mark>882</mark> 90465600 5.776082774 +43	61/36043e 425558771434	1? 1498864e
10	18	90	9.430298923 +112	3 255 59280477 1.07573451(+79	7052413e 027871200629	1? 9339068e

16	30	240	3.229246017 +354	7 998 5540075 ⁷ 2.450646102 +259	1522483e 271441678267	1? 7620602e
n	2 * (n - 1)	n * (n - 1)	(2 * (n - 1)) ^ (n * (n - 1))	<= (((2 * (n - 1))!) ^ (n / 2))	?	1?

Chapter 4. Planner configuration

4.1. Overview

Solving a planning problem with Drools Planner consists out of 5 steps:

- 1. Model your planning problem as a class that implements the interface <code>solution</code>, for example the class <code>NQueens</code>.
- 2. Configure a solver, for example a first fit and tabu search solver for any NQueens instance.
- 3. Load a problem data set from your data layer, for example a 4 Queens instance. Set it as the planning problem on the Solver with Solver.setPlanningProblem(...).
- 4. Solve it with Solver.solve().
- 5. Get the best solution found by the Solver with Solver.getBestSolution().

4.2. Solver configuration

4.2.1. Solver configuration by XML file

You can build a solver instance with the XmlsolverFactory. Configure it with a solver configuration XML file:

```
XmlSolverFactory solverFactory = new XmlSolverFactory();
      solverFactory.configure("/org/drools/planner/examples/nqueens/solver/
nqueensSolverConfig.xml");
      Solver solver = solverFactory.buildSolver();
```

A solver configuration file looks something like this:

```
</scoreDirectorFactory>
<!-- Configure the optimization algorithm(s) -->
<termination>
...
</termination>
<constructionHeuristic>
...
</constructionHeuristic>
<localSearch>
...
</localSearch>
</solver>
```

Notice the 3 parts in it:

- · Define the model
- Define the score function
- Configure the optimization algorithm(s)

We 'll explain these various parts of a configuration later in this manual.

Drools Planner makes it relatively easy to switch optimization algorithm(s) just by changing the configuration. There's even a Benchmark utility which allows you to play out different configurations against each other and report the most appropriate configuration for your problem. You could for example play out tabu search versus simulated annealing, on 4 queens and 64 queens.

4.2.2. Solver configuration by Java API

As an alternative to the XML file, a solver configuration can also be configured with the SolverConfig API:

```
SolverConfig solverConfig = new SolverConfig();
```

```
solverConfig.setSolutionClass(NQueens.class);
Set<Class<?>> planningEntityClassSet = new HashSet<Class<?>>();
planningEntityClassSet.add(Queen.class);
solverConfig.setPlanningEntityClassSet(planningEntityClassSet);
```

```
ScoreDirectorFactoryConfig scoreDirectorFactoryConfig = solverConfig.getScoreDirectorFactoryConfig.setScoreDefinitionType(ScoreDirectorFactoryConfig.ScoreDefinitionType)
```

```
Arrays.asList("/org/drools/planner/examples/nqueens/solver/
nQueensScoreRules.drl"));
```

It is highly recommended to configure by XML file instead of this API. To dynamically configure a value at runtime, use the XML file as a template and extract the <code>solverConfig()</code> to configure the dynamic value at runtime:

```
XmlSolverFactory solverFactory = new XmlSolverFactory();
      solverFactory.configure("/org/drools/planner/examples/nqueens/solver/
nqueensSolverConfig.xml");
```

```
SolverConfig solverConfig = solverFactory.getSolverConfig();
solverConfig.getTerminationConfig().setMaximumMinutesSpend(userInput);
Solver solver = solverConfig.buildSolver();
```

4.3. Model your planning problem

4.3.1. Is this class a problem fact or planning entity?

Look at a dataset of your planning problem. You 'll recognize domain classes in there, each of which is one of these:

- A unrelated class: not used by any of the score constraints. From a planning standpoint, this data is obsolete.
- A problem fact class: used by the score constraints, but does NOT change during planning (as long as the problem stays the same). For example: Bed, Room, Shift, Employee, Topic, Period, ...
- A planning entity class: used by the score constraints and changes during planning. For example: BedDesignation, ShiftAssignment, Exam, ...

Ask yourself: What class changes during planning? Which class has variables that I want the *solver* to choose for me? That class is a planning entity. Most use cases have only 1 planning entity class.

Note

In *real-time planning*, problem facts can change during planning, because the problem itself changes. However, that doesn't make them planning entities.

In Drools Planner all problems facts and planning entities are plain old JavaBeans (POJO's). You can load them from a database (JDBC/JPA/JDO), an XML file, a data repository, a noSQL cloud, ...: Drools Planner doesn't care.

4.3.2. Problem fact

A problem fact is any JavaBean (POJO) with getters that does not change during planning. Implementing the interface Serializable is recommended (but not required). For example in n queens, the columns and rows are problem facts:

```
public class Column implements Serializable {
    private int index;
    // ... getters
}
```

```
public class Row implements Serializable {
    private int index;
    // ... getters
}
```

A problem fact can reference other problem facts of course:

```
public class Course implements Serializable {
    private String code;
    private Teacher teacher; // Other problem fact
    private int lectureSize;
    private int minWorkingDaySize;
    private List<Curriculum> curriculumList; // Other problem facts
    private int studentSize;
    // ... getters
```

}

A problem fact class does *not* require any Planner specific code. For example, you can reuse your domain classes, which might have JPA annotations.

Note

Generally, better designed domain classes lead to simpler and more efficient score constraints. Therefore, when dealing with a messy legacy system, it can sometimes be worth it to convert the messy domain set into a planner specific POJO set first. For example: if your domain model has 2 Teacher instances for the same teacher that teaches at 2 different departments, it's hard to write a correct score constraint that constrains a teacher's spare time.

Alternatively, you can sometimes also introduce a cached problem fact to enrich the domain model for planning only.

4.3.3. Planning entity and planning variables

4.3.3.1. Planning entity

A planning entity is a JavaBean (POJO) that changes during solving, for example a Queen that changes to another row. A planning problem has multiple planning entities, for example for a single n queens problem, each Queen is a planning entity. But there's usually only 1 planning entity class, for example the Queen class.

A planning entity class needs to be annotated with the <code>@PlanningEntity</code> annotation.

Each planning entity class has 1 or more *planning variables*. It usually also has 1 or more *defining* properties. For example in n queens, a *Queen* is defined by its *Column* and has a planning variable Row. This means that a Queen's column never changes during solving, while its row does change.

```
@PlanningEntity
public class Queen {
    private Column column;
    // Planning variables: changes during planning, between score calculations.
    private Row row;
    // ... getters and setters
}
```

A planning entity class can have multiple planning variables. For example, a Lecture is defined by its Course and its index in that course (because 1 course has multiple lectures). Each Lecture needs to be scheduled into a Period and a Room so it has 2 planning variables (period and room). For example: the course Mathematics has 8 lectures per week, of which the first lecture is Monday morning at 08:00 in room 212.

```
@PlanningEntity
public class Lecture {
    private Course course;
    private int lectureIndexInCourse;
    // Planning variables: changes during planning, between score calculations.
    private Period period;
    private Room room;
    // ...
}
```

The solver configuration also needs to be made aware of each planning entity class:

```
<solver>
...
.planningEntityClass>org.drools.planner.examples.nqueens.domain.Queen</
planningEntityClass>
...
</solver>
```

Some uses cases have multiple planning entity classes. For example: route freight and trains into railway network arcs, where each freight can use multiple trains over its journey and each train can carry multiple freights per arc. Having multiple planning entity classes directly raises the implementation complexity of your use case.

Note

Do not create unnecessary planning entity classes. This leads to difficult Move implementations and slower score calculation.

For example, do not create a planning entity class to hold the total free time of a teacher, which needs to be kept up to date as the Lecture planning entities change. Instead, calculate the free time in the score constraints and put the result per teacher into a logically inserted score object.

If historic data needs to be considered too, then create problem fact to hold the historic data up to, but *not including*, the planning window (so it doesn't change when a planning entity changes) and let the score constraints take it into account.

4.3.3.2. Planning entity difficulty

Some optimization algorithms work more efficiently if they have an estimation of which planning entities are more difficult to plan. For example: in bin packing bigger items are harder to fit, in course scheduling lectures with more students are more difficult to schedule and in n queens the middle queens are more difficult.

Therefore, you can set a difficultyComparatorClass to the @PlanningEntity annotation:

```
@PlanningEntity(difficultyComparatorClass = CloudProcessDifficultyComparator.class)
public class CloudProcess {
    // ...
}
```

```
public class CloudProcessDifficultyComparator implements Comparator<CloudProcess> {
    public int compare(CloudProcess a, CloudProcess b) {
        return new CompareToBuilder()
            .append(a.getRequiredMultiplicand(), b.getRequiredMultiplicand())
            .append(a.getId(), b.getId())
            .toComparison();
    }
}
```

Note

If you have multiple planning entity classes, the difficultyComparatorClass needs to implement a Comparator of a common superclass (for example Comparator<Object>) and be able to handle comparing instances of those different classes.

Alternatively, you can also set a difficultyWeightFactoryClass to the @PlanningEntity annotation, so you have access to the rest of the problem facts from the solution too:

@PlanningEntity(difficultyWeightFactoryClass = QueenDifficultyWeightFactory.class)
public class Queen {

```
// ...
```

```
public interface PlanningEntityDifficultyWeightFactory {
    Comparable createDifficultyWeight(Solution solution, Object planningEntity);
}
```

```
public class QueenDifficultyWeightFactory implements PlanningEntityDifficultyWeightFactory {
    public Comparable createDifficultyWeight(Solution solution, Object planningEntity) {
        NQueens nQueens = (NQueens) solution;
        Queen queen = (Queen) planningEntity;
        int distanceFromMiddle = calculateDistanceFromMiddle(nQueens.getN(), queen.getColumnInd
        return new QueenDifficultyWeight(queen, distanceFromMiddle);
    }
    // ...
    public static class QueenDifficultyWeight implements Comparable<QueenDifficultyWeight> {
        private final Queen queen;
        private final int distanceFromMiddle;
        public QueenDifficultyWeight(Queen queen, int distanceFromMiddle) {
            this.queen = queen;
            this.distanceFromMiddle = distanceFromMiddle;
        }
        public int compareTo(QueenDifficultyWeight other) {
            return new CompareToBuilder()
                // The more difficult queens have a lower distance to the middle
                       .append(other.distanceFromMiddle, distanceFromMiddle) //
Decreasing
                  .append(queen.getColumnIndex(), other.queen.getColumnIndex())
                    .toComparison();
        }
    }
}
```

None of the current planning variable state may be used to compare planning entities. They are likely to be null anyway. For example, a Queen's row variable may not be used.

4.3.3.3. Planning variable

A planning variable is a property (including getter and setter) on a planning entity. It changes during planning. For example, a Queen's row property is a planning variable. Note that even though a Queen's row property changes to another Row during planning, no Row instance itself is changed. A planning variable points to a planning value.

A planning variable getter needs to be annotated with the <code>@PlanningVariable</code> annotation. Furthermore, it needs a <code>@ValueRange</code> annotation too.

```
@PlanningEntity
public class Queen {
    private Row row;
    // ...
    @PlanningVariable
    @ValueRange(type = ValueRangeType.FROM_SOLUTION_PROPERTY, solutionProperty = rowList")
    public Row getRow() {
        return row;
    }
    public void setRow(Row row) {
        this.row = row;
    }
}
```

4.3.3.4. When is a planning entity initialized?

A planning entity is considered initialized if all its planning variables are initialized.

By default, a planning variable is considered initialized if its value is not null.

4.3.4. Planning value and planning value ranges

4.3.4.1. Planning value

A planning value is a possible value for a planning variable. Usually, a planning value is problem fact, but it can also be any object, for example a double. It can even be another planning entity or even a interface implemented by a planning entity and a problem fact.

A planning value range is the set of possible planning values for a planning variable. This set can be a discrete (for example row 1, 2, 3 or 4) or continuous (for example any double between 0.0 and 1.0). There are several ways to define the value range of a planning variable with the @ValueRange annotation. If null is a valid planning value, it should be included in the value range and the default way to detect uninitialized planning variables must be changed (TODO for now, a *workaround* [https:// issues.jboss.org/browse/JBRULES-3317] is needed).

4.3.4.2. Planning value range

4.3.4.2.1. ValueRange from Solution property

All instances of the same planning entity class share the same set of possible planning values for that planning variable. This is the most common way to configure a value range.

The solution implementation has property which returns a collection. Any value from that collection is a possible planning value for this planning variable.

```
@PlanningVariable
@ValueRange(type = ValueRangeType.FROM_SOLUTION_PROPERTY, solutionProperty = "rowList")
public Row getRow() {
    return row;
}
```

```
public class NQueens implements Solution<SimpleScore> {
    // ...
    public List<Row> getRowList() {
        return rowList;
    }
}
```

4.3.4.2.2. ValueRange from planning entity

Each planning entity has its own set of possible planning values for a planning variable. For example, if a teacher can **never** teach in a room that does not belong to his department, lectures of that teacher can limit their room value range to the rooms of his department.

```
@PlanningVariable
@ValueRange(type = ValueRangeType.FROM_PLANNING_ENTITY_PROPERTY, planningEntityProperty =
public Room getRoom() {
    return room;
    }
public List<Room> getPossibleRoomList() {
    return getCourse().getTeacher().getPossibleRoomList();
```

}

Never use this to enforce a soft constraint (or even a hard constraint when the problem might not have a feasible solution). For example: *Unless there is no other way*, a teacher can not teach in a room that does not belong to his department. In this case, the teacher should *not* be limited in his room value range (because sometimes there is no other way).

Note

By limiting the value range specifically of 1 planning entity, you are effectively making a *build-in hard constraint*. This can be a very good thing, as the number of possible solutions is severely lowered. But this can also be a bad thing because it takes away the freedom of the optimization algorithms to temporarily break such a hard constraint.

A planning entity should *not* use other planning entities to determinate its value range. That would only try to make it solve the planning problem itself and interfere with the optimization algorithms.

4.3.4.2.3. ValueRange undefined

Leaves the value range undefined. Some optimization algorithms do not support this value range.

```
@PlanningVariable
@ValueRange(type = ValueRangeType.UNDEFINED)
public Row getRow() {
    return row;
}
```

4.3.4.2.4. Combining ValueRanges

Value ranges can be combined, for example:

```
@PlanningVariable(...)
@ValueRanges({
    @ValueRange(type = ValueRangeType.FROM_SOLUTION_PROPERTY, solutionProperty = "compa
@ValueRange(type = ValueRangeType.FROM_PLANNING_ENTITY_PROPERTY, planningEntityProp
public Car getCar() {
    return car;
}
```

4.3.4.2.5. A ValueRange which includes other planning entities

In some cases (such as in chaining), the planning value itself is sometimes another planning entity. In such cases, it's often required that a planning entity is only eligible as a planning value if it's initialized:

```
@PlanningVariable
@ValueRange(type = ValueRangeType.FROM_SOLUTION_PROPERTY, solutionProperty = "copList", exc
public Cop getPartner() {
    return partner;
}
```

TODO: this is likely to change in the future (*jira* [https://issues.jboss.org/browse/JBRULES-3408]), as it should support specific planning variable initialization too.

4.3.4.2.6. Chained

Some use cases, such as TSP and Vehicle Routing, require *chaining*. This means the planning entities point to each other and form a chain.

A planning variable that is chained either:

- Directly points to a planning fact, which is called an anchor.
- Points to another planning entity with the same planning variable, which recursively points to an anchor.

Here are some example of valid and invalid chains:

Chain principles

Every initialized planning entity is part of an open-ended chain that begins from an anchor. A valid model means that:

- A chain is never a loop. The tail is always open.
- Every chain always has exactly 1 anchor. The anchor is a problem fact, never a planning entity.
- A chain is never a tree, it is always a line. Every anchor or planning entity has at most 1 trailing planning entity.
- Every initialized planning entity is part of a chain.
- An anchor with no planning entities pointing to it, is also considered a chain.

Note

If your constraints dictate a closed chain, model it as an open-ended chain (which is easier to persist in a database) and implement a score constraint for the last entity back to the anchor.

The optimization algorithms and build-in MoveFactory's do chain correction to guarantee that the model stays valid:

Chain correction

Changing 1 planning variable may inflict up to 2 chain corrections.

```
public class Domicile ... implements Appearance {
```

```
...
public City getCity() {...}
}
```

The anchor (which is a problem fact) and the planning entity implement a common interface, for example TSP's Appearance:

```
public interface Appearance {
    City getCity();
}
```

That interface is the return type of the planning variable. Furthermore, the planning variable is chained. For example TSP's visit (in vehicle routing it is the customer):

```
@PlanningEntity
public class Visit ... implements Appearance {
    . . .
   public City getCity() {...}
   @PlanningVariable(chained = true)
    @ValueRanges({
            @ValueRange(type = ValueRangeType.FROM_SOLUTION_PROPERTY, solutionProperty = "domic
            @ValueRange(type = ValueRangeType.FROM_SOLUTION_PROPERTY, solutionProperty = "visit
                    excludeUninitializedPlanningEntity = true)})
   public Appearance getPreviousAppearance() {
        return previousAppearance;
    }
   public void setPreviousAppearance(Appearance previousAppearance) {
        this.previousAppearance = previousAppearance;
    }
}
```

Notice how 2 value ranges need to be combined:

• The value range which holds the anchors, for example <code>domicileList</code>.

• The value range which holds the initialized planning entities, for example <code>visitList</code>. This always requires an enabled <code>excludeUninitializedPlanningEntity</code>, because an initialized entity should never point to an uninitialized entity: that would break the principle that every chain must have an anchor.

4.3.4.3. Planning value strength

Some optimization algorithms work more efficiently if they have an estimation of which planning values are stronger, which means they are more likely to satisfy a planning entity. For example: in bin packing bigger containers are more likely to fit an item and in course scheduling bigger rooms are less likely to break the student capacity constraint.

Therefore, you can set a strengthComparatorClass to the @PlanningVariable annotation:

```
@PlanningVariable(strengthComparatorClass = CloudComputerStrengthComparator.class)
// ...
public CloudComputer getComputer() {
    // ...
}
```

```
public class CloudComputerStrengthComparator implements Comparator<CloudComputer> {
    public int compare(CloudComputer a, CloudComputer b) {
        return new CompareToBuilder()
            .append(a.getMultiplicand(), b.getMultiplicand())
            .append(b.getCost(), a.getCost()) // Descending (but this
        is debatable)
            .append(a.getId(), b.getId())
            .toComparison();
    }
}
```

Note

If you have multiple planning value classes in the same value range, the strengthComparatorClass needs to implement a Comparator of a common superclass (for example Comparator<Object>) and be able to handle comparing instances of those different classes.

Alternatively, you can also set a strengthWeightFactoryClass to the @PlanningVariable annotation, so you have access to the rest of the problem facts from the solution too:

```
@PlanningVariable(strengthWeightFactoryClass = RowStrengthWeightFactory.class)
// ...
public Row getRow() {
    // ...
}
```

public interface PlanningValueStrengthWeightFactory {

Comparable createStrengthWeight(Solution solution, Object planningValue);

}

```
public class RowStrengthWeightFactory implements PlanningValueStrengthWeightFactory {
   public Comparable createStrengthWeight(Solution solution, Object planningValue) {
        NQueens nQueens = (NQueens) solution;
        Row row = (Row) planningValue;
        int distanceFromMiddle = calculateDistanceFromMiddle(nQueens.getN(), row.getIndex());
        return new RowStrengthWeight(row, distanceFromMiddle);
    }
    // ...
   public static class RowStrengthWeight implements Comparable<RowStrengthWeight> {
        private final Row row;
        private final int distanceFromMiddle;
        public RowStrengthWeight(Row row, int distanceFromMiddle) {
            this.row = row;
            this.distanceFromMiddle = distanceFromMiddle;
        }
        public int compareTo(RowStrengthWeight other) {
            return new CompareToBuilder()
                    // The stronger rows have a lower distance to the middle
                       .append(other.distanceFromMiddle, distanceFromMiddle) //
Decreasing (but this is debatable)
                    .append(row.getIndex(), other.row.getIndex())
                    .toComparison();
        }
    }
```

}

None of the current planning variable state in any of the planning entities may be used to compare planning values. They are likely to be null anyway. For example, None of the row variables of any Queen may be used to determine the strength of a Row.

4.3.5. Planning problem and planning solution

4.3.5.1. Planning problem instance

A dataset for a planning problem needs to be wrapped in a class for the solver to solve. You must implement this class. For example in n queens, this in the NQueens class which contains a Column list, a Row list and a Queen list.

A planning problem is actually a unsolved planning solution or - stated differently - an uninitialized solution. Therefor, that wrapping class must implement the solution interface. For example in n queens, that NQueens class implements solution, yet every Queen in a fresh NQueens class is not yet assigned to a Row (their row property is null). So it's not a feasible solution. It's not even a possible solution. It's an uninitialized solution.

4.3.5.2. The solution interface

You need to present the problem as a *solution* instance to the *solver*. So you need to have a class that implements the *solution* interface:

```
public interface Solution<S extends Score> {
    S getScore();
    void setScore(S score);
    Collection<? extends Object> getProblemFacts();
    Solution<S> cloneSolution();
}
```

For example, an NQueens instance holds a list of all columns, all rows and all Queen instances:

```
public class NQueens implements Solution<SimpleScore> {
    private int n;
    // Problem facts
    private List<Column> columnList;
    private List<Row> rowList;
```

```
// Planning entities
private List<Queen> queenList;
// ...
}
```

4.3.5.3. The getScore and setScore methods

A solution requires a score property. The score property is null if the solution is uninitialized or if the score has not yet been (re)calculated. The score property is usually typed to the specific score implementation you use. For example, NQueens uses a SimpleScore:

```
public class NQueens implements Solution<SimpleScore> {
    private SimpleScore score;
    public SimpleScore getScore() {
        return score;
    }
    public void setScore(SimpleScore score) {
        this.score = score;
    }
    // ...
}
```

Most use cases use a HardAndSoftScore instead:

```
public class CurriculumCourseSchedule implements Solution<HardAndSoftScore> {
    private HardAndSoftScore score;
    public HardAndSoftScore getScore() {
        return score;
    }
    public void setScore(HardAndSoftScore score) {
        this.score = score;
    }
    // ...
}
```

See the Score calculation section for more information on the score implementations.

4.3.5.4. The getProblemFacts method

The method is only used if Drools is used for score calculation. Other score directors do not use it.

All objects returned by the getProblemFacts() method will be asserted into the Drools working memory, so the score rules can access them. For example, NQueens just returns all Column and Row instances.

```
public Collection<? extends Object> getProblemFacts() {
    List<Object> facts = new ArrayList<Object>();
    facts.addAll(columnList);
    facts.addAll(rowList);
    // Do not add the planning entity's (queenList) because that will be
done automatically
    return facts;
}
```

All planning entities are automatically inserted into the Drools working memory. Do not add them in the method getProblemFacts().

The method getProblemFacts() is not called much: at most only once per solver phase per solver thread.

4.3.5.5. Cached problem fact

A cached problem fact is a problem fact that doesn't exist in the real domain model, but is calculated before the <code>Solver</code> really starts solving. The method <code>getProblemFacts()</code> has the chance to enrich the domain model with such cached problem facts, which can lead to simpler and faster score constraints.

For example in examination, a cache problem fact TopicConflict is created for every 2 Topic's which share at least 1 Student.

```
public Collection<? extends Object> getProblemFacts() {
   List<Object> facts = new ArrayList<Object>();
   // ...
   facts.addAll(calculateTopicConflictList());
   // ...
   return facts;
}
private List<TopicConflict> calculateTopicConflictList() {
   List<TopicConflict> topicConflictList = new ArrayList<TopicConflict>();
   for (Topic leftTopic : topicList) {
```

```
for (Topic rightTopic : topicList) {
            if (leftTopic.getId() < rightTopic.getId()) {</pre>
                int studentSize = 0;
                for (Student student : leftTopic.getStudentList()) {
                     if (rightTopic.getStudentList().contains(student)) {
                         studentSize++;
                     }
                }
                if (studentSize > 0) {
                    topicConflictList.add(new TopicConflict(leftTopic, rightTopic, students)
                }
            }
        }
    }
   return topicConflictList;
}
```

Any score constraint that needs to check if no 2 exams have a topic which share a student are being scheduled close together (depending on the constraint: at the same time, in a row or in the same day), can simply use the TopicConflict instance as a problem fact, instead of having to combine every 2 student instances.

4.3.5.6. The cloneSolution method

Most optimization algorithms use the cloneSolution() method to clone the solution each time they encounter a new best solution (so they can recall it later) or to work with multiple solutions in parallel.

The NQueens implementation only deep clones all Queen instances. When the original solution is changed during planning, by changing a Queen, the clone stays the same.

```
/**
 * Clone will only deep copy the {@link #queenList}.
*/
public NQueens cloneSolution() {
   NQueens clone = new NQueens();
    clone.id = id;
    clone.n = n;
    clone.columnList = columnList;
    clone.rowList = rowList;
   List<Queen> clonedQueenList = new ArrayList<Queen>(queenList.size());
    for (Queen queen : queenList) {
        clonedQueenList.add(queen.clone());
    }
    clone.queenList = clonedQueenList;
    clone.score = score;
    return clone;
```

}

The cloneSolution() method should only deep clone the planning entities. Notice that the problem facts, such as Column and Row are normally not cloned: even their List instances are not cloned.

Note

If you were to clone the problem facts too, then you'd have to make sure that the new planning entity clones also refer to the new problem facts clones used by the solution. For example, if you 'd clone all Row instances, then each Queen clone and the NQueens clone itself should refer to the same set of new Row clones.

4.3.5.7. Build an uninitialized solution

Build a Solution instance to represent your planning problem, so you can set it on the Solver as the planning problem to solve. For example in n queens, an NQueens instance is created with the required Column and Row instances and every Queen set to a different column and every row set to null.

```
private NQueens createNQueens(int n) {
    NQueens nQueens = new NQueens();
    nQueens.setId(0L);
    nQueens.setN(n);
    List<Column> columnList = new ArrayList<Column>(n);
    for (int i = 0; i < n; i++) {</pre>
        Column column = new Column();
        column.setId((long) i);
        column.setIndex(i);
        columnList.add(column);
    }
    nOueens.setColumnList(columnList);
    List<Row> rowList = new ArrayList<Row>(n);
    for (int i = 0; i < n; i++) {</pre>
        Row row = new Row();
        row.setId((long) i);
        row.setIndex(i);
        rowList.add(row);
    }
    nQueens.setRowList(rowList);
    List<Queen> queenList = new ArrayList<Queen>(n);
    long id = 0;
    for (Column column : columnList) {
        Queen queen = new Queen();
        queen.setId(id);
```

```
id++;
    queen.setColumn(column);
    // Notice that we leave the PlanningVariable properties (row) on null
    queenList.add(queen);
    }
    nQueens.setQueenList(queenList);
    return nQueens;
}
```

Figure 4.1. Uninitialized solution for the 4 queens puzzle

Usually, most of this data comes from your data layer, and your *solution* implementation just aggregates that data and creates the uninitialized planning entity instances to plan:

```
private void createLectureList(CurriculumCourseSchedule schedule) {
    List<Course> courseList = schedule.getCourseList();
    List<Lecture> lectureList = new ArrayList<Lecture>(courseList.size());
    for (Course course : courseList) {
        for (int i = 0; i < course.getLectureSize(); i++) {
            Lecture lecture = new Lecture();
            lecture.setCourse(course);
            lecture.setLectureIndexInCourse(i);
            // Notice that we leave the PlanningVariable properties
    (period and room) on null
            lectureList.add(lecture);
        }
        schedule.setLectureList(lectureList);
    }
}</pre>
```

4.4. Use the Solver

4.4.1. The Solver interface

A solver implementation will solve your planning problem.

```
public interface Solver {
    void setPlanningProblem(Solution planningProblem);
    void solve();
    Solution getBestSolution();
    // ...
}
```

A solver can only solve 1 planning problem instance at a time. A solver should only be accessed from a single thread, except for the methods that are specifically javadocced as being thread-safe. It's build with a SolverFactory, do not implement or build it yourself.

4.4.2. Solving a problem

Solving a problem is quite easy once you have:

- A solver build from a solver configuration
- A solution that represents the planning problem instance

Just set the planning problem, solve it and extract the best solution:

```
solver.setPlanningProblem(planningProblem);
solver.solve();
Solution bestSolution = solver.getBestSolution();
```

For example in n queens, the method getBestSolution() will return an NQueens instance with every Queen assigned to a Row.

Figure 4.2. Best solution for the 4 queens puzzle in 8 ms (also an optimal solution)

The solve() method can take a long time (depending on the problem size and the solver configuration). The solver will remember (actually clone) the best solution it encounters during its solving. Depending on a number factors (including problem size, how time the solver has, the solver configuration, ...), that best solution will be a feasible or even an optimal solution.

Note

The Solution instance given to the method setPlanningProblem() will be changed by the solver, but it do not mistake it for the best solution.

The solution instance returned by the method getBestSolution() will most likely be a clone of the instance given to the method setPlanningProblem(), which means it's a different instance.

Note

The solution instance given to the method setPlanningProblem() does not need to be uninitialized. It can be partially or fully initialized, which is likely in repeated planning.

4.4.3. Environment mode: Are there bugs in my code?

The environment mode allows you to detect common bugs in your implementation. It does not affect the logging level.

You can set the environment mode in the solver configuration XML file:

```
<solver>
<environmentMode>DEBUG</environmentMode>
...
</solver>
```

A solver has a single Random instance. Some solver configurations use the Random instance a lot more than others. For example simulated annealing depends highly on random numbers, while tabu search only depends on it to deal with score ties. The environment mode influences the seed of that Random instance.

There are 4 environment modes:

4.4.3.1. TRACE

The trace mode is reproducible (see the reproducible mode) and also turns on all assertions (such as assert that the delta based score is uncorrupted) to fail-fast on rule engine bugs.

The trace mode is very slow (because it doesn't rely on delta based score calculation).

4.4.3.2. DEBUG

The debug mode is reproducible (see the reproducible mode) and also turns on most assertions (such as assert that the undo Move is uncorrupted) to fail-fast on a bug in your Move implementation, your score rule, ...

The debug mode is slow.

It's recommended to write a test case which does a short run of your planning problem with debug mode on.

4.4.3.3. REPRODUCIBLE (default)

The reproducible mode is the default mode because it is recommended during development. In this mode, 2 runs in the same Planner version will execute the same code in the same order. **Those 2 runs will have the same result**, except if they rely on time based termination and they have a sufficiently large difference in allocated CPU time. This allows you to consistently reproduce bugs. It also allows you to benchmark certain refactorings (such as a score constraint optimization) fairly across runs.

The reproducible mode is not much slower than the production mode. If your production environment requires reproducibility, use it in production too.

In practice, this mode uses the default random seed, and it also disables certain concurrency optimizations (such as work stealing).

4.4.3.4. PRODUCTION

The production mode is the fastest and the most robust, but not reproducible. It is recommended for a production environment.

The random seed is different on every run, which makes it more robust against an unlucky random seed. An unlucky random seed gives a bad result on a certain data set with a certain solver configuration. Note that in most use cases the impact of the random seed is relatively low on the result (even with simulated annealing). An occasional bad result is far more likely caused by another issue (such as a score trap).

4.4.4. Logging level: What is the solver doing?

The best way to illuminate the black box that is a solver, is to play with the logging level:

- ERROR: When something is wrong, Planner fails fast: it throws a subclass of RuntimeException with a detailed message to the calling code, but does not log an error message to avoid duplicate log messages. If the calling code doesn't catch and eat that RuntimeException, a Thread's default ExceptionHandler will log it as an error anyway.
- WARN: Log suspicious circumstances.

- INFO: Log every phase and the solver itself.
- DEBUG: Log every step of every phase.
- TRACE: Log every move of every step of every phase.

For example, set it to DEBUG logging, to see when the phases end and how fast steps are taken:

```
INFO Solving started: time spend (0), score (null), new best score (null),
random seed (0).
         Step index (0), time spend (1), score (0), initialized planning entity
DEBUG
 (col2@row0).
        Step index (1), time spend (3), score (0), initialized planning entity
DEBUG
 (coll@row2).
DEBUG Step index (2), time spend (4), score (0), initialized planning entity
 (col3@row3).
DEBUG
           Step index (3), time spend (5), score (-1), initialized planning
entity (col0@row1).
INFO Phase constructionHeuristic finished: step total (4), time spend (6), best
score (-1).
DEBUG
          Step index (0), time spend (10), score (-1),
                                                             best score (-1),
accepted move size (12) for picked step (coll@row2 => row3).
        Step index (1), time spend (12), score (0), new best score (0), accepted
DEBUG
move size (12) for picked step (col3@row3 => row2).
INFO Phase localSearch ended: step total (2), time spend (13), best score (0).
INFO Solving ended: time spend (13), best score (0), average calculate count
per second (4846).
```

All time spends are in milliseconds.

Everything is logged to *SLF4J* [http://www.slf4j.org/], which is a simple logging facade that can delegate any log to Logback, Apache Commons Logging, Log4j or java.util.logging. Add a dependency to the logging adaptor for your logging framework of choice. If you're not using any logging framework yet, you can use Logback by adding this Maven dependency:

```
<dependency>
<groupId>ch.qos.logback</groupId>
<artifactId>logback-classic</artifactId>
<version>1.x</version>
</dependency>
```

Configure the logging level on the package org.drools.planner. For example:

In Logback, configure it in your logback.xml file:

<configuration>

```
<logger name="org.drools.planner" level="debug"/>
...
<configuration>
```

In Log4J, configure it in your log4j.xml file:

```
<leg4j:configuration xmlns:log4j="http://jakarta.apache.org/log4j/">
</category name="org.drools.planner">
</priority value="debug" />
</category>
...
</log4j:configuration>
```
Chapter 5. Score calculation

5.1. Score terminology

5.1.1. What is a score?

Every initialized <code>Solution</code> has a score. That score is an objective way to compare 2 solutions: the solution with the highest score is better. The <code>Solver</code> aims to find the <code>Solution</code> with the highest score. The *best solution* is the <code>Solution</code> with the highest score that it has encountered during solving, so it might be the *optimal solution*.

Planner cannot automatically know which *solution* your business prefers, so you need to tell it how to calculate the score of a *solution*.

5.1.2. Negative and positive constraints

Most planning problems use negative scores, because they have negative constraints. In that case, the score is usually the sum of the weight of the negative constraints being broken, with an perfect score of 0. This explains why the score of a solution of 4 queens is the negative (and not the positive!) of the number of queen couples which can attack each other.

Negative and positive constraints can be combined, even in the same level.

Don't presume your business knows all its score constraints in advance. Expect score constraints to be added or changed after the first releases.

When a constraint activates (because the negative constraint is broken or the positive constraint is fulfilled) on a certain planning entity set, it is called a *constraint occurrence*.

5.1.3. Score constraint weighting

Note

i

Not all score constraints are equally important. If breaking one constraint is equally bad as breaking another constraint x times, then those 2 constraints have a different weight (but they are in the same score level). For example in vehicle routing, you can make 5 broken "avoid crossroads" soft constraints count as much as 1 broken "avoid highways at rush hour" soft constraint.

The weight of a constraint occurrence is often dynamically based on the planning entities involved. For example in cloud balance: the weight of the soft constraint occurrence for an active <code>Computer</code> is the <code>cost</code> of that <code>Computer</code>.

Note

Your business will probably tell you that your hard constraints all have the same weight, because they cannot be broken (so their weight does not matter). This is not true and it could create a *score trap*. For example in cloud balance: if a Computer has 7 CPU too little for its Processes, then it must be weighted 7 times as much as if it had only 1 CPU too little. This way, there is an incentive to move a Process with 6 CPU or less away from that Computer.

5.1.4. Score level

Sometimes score constraints are in different level. If breaking one constraint is always worse than another, no matter how much another constraint is broken, then those 2 constraints are in a different level.

Most use cases have 2 score levels: hard and soft. When comparing 2 scores, the higher score level gets compared first. If those differ, the lower score levels are ignored. For example: a score that breaks 0 hard constraints and 1000000 soft constraints is better than a score that breaks 1 hard constraint and 0 soft constraints.

5.1.5. The score interface

A score is represented by the score interface, which naturally extends Comparable:

```
public interface Score<...> extends Comparable<...> {
    ...
}
```

The score implementation to use depends on your use case. Your score might not efficiently fit in a single double value. Planner has several build-in Score implementations, but you can also implement a custom Score too. Most use cases will just use the build-in HardAndSoftScore.

The score implementation (for example DefaultHardAndSoftScore) must be the same throughout a solver runtime. The score implementation is configured in the solver configuration as a ScoreDefinition:

```
<scoreDirectorFactory>
    <scoreDefinitionType>HARD_AND_SOFT</scoreDefinitionType>
    ...
</scoreDirectorFactory>
```

Based on your score constraints and score level requirements, you 'll choose a certain ScoreDefinition:

5.2. Choose a Score definition

5.2.1. SimpleScore

The SimpleScoreDefinition defines the Score as a SimpleScore which has a single int value, for example -123. It has 1 score level.

```
<scoreDirectorFactory>
  <scoreDefinitionType>SIMPLE</scoreDefinitionType>
   ...
</scoreDirectorFactory>
```

Variants:

• SimpleDoubleScore: Uses a double value instead of an int value. Configure it with scoreDefinitionType SIMPLE_DOUBLE.

5.2.2. HardAndSoftScore (recommended)

The HardAndSoftScoreDefinition defines the Score as a HardAndSoftScore which has a hard int value and a soft int value, for example -123hard/-456soft. It has 2 score levels (hard and soft).

```
<scoreDirectorFactory>
<scoreDefinitionType>HARD_AND_SOFT</scoreDefinitionType>
...
</scoreDirectorFactory>
```

Variants:

• HardAndSoftLongScore: Uses long values instead of int values. Configure it with scoreDefinitionType HARD_AND_SOFT_LONG.

5.2.3. Implementing a custom Score

The **ScoreDefinition** interface defines the score representation.

To implement a custom Score, you 'll also need to implement a custom ScoreDefinition. Extend AbstractScoreDefinition (preferable by copy pasting HardAndSoftScoreDefinition or SimpleScoreDefinition) and start from there.

Then hook you custom ScoreDefinition in your SolverConfig.xml:

<scoreDirectorFactory>

efinitionClass>org.drools.planner.examples.my.score.definition.MyScoreDefinition</

```
OTEDETITICIONCIASS>
```

. . .

</scoreDirectorFactory>

5.3. Calculate the score

5.3.1. Score calculation types

There are several ways to calculate the score of a Solution:

- Simple Java score calculation: implement a single Java method
- Incremental Java score calculation: implement multiple Java methods
- Drools score calculation: implement score rules

Every score calculation type can use any Score definition. For example, simple score calculation can output a HardAndSoftScore.

All score calculation types are Object Orientated and can reuse existing Java code.

5.3.2. Simple Java score calculation

A simple way to implement your score calculation in Java.

- · Advantages:
 - Plain old Java: no learning curve
 - · Opportunity to delegate score calculation to an existing code base or legacy system
- Disadvantages:
 - Slower and less scalable
 - Because there is no incremental score calculation

Just implement one method of the interface SimpleScoreCalculator:

```
public interface SimpleScoreCalculator<Sol extends Solution> {
    Score calculateScore(Sol solution);
```

}

For example in n queens:

```
public class NQueensSimpleScoreCalculator implements SimpleScoreCalculator<NQueens> {
    public SimpleScore calculateScore(NQueens nQueens) {
        int n = nQueens.getN();
        List<Queen> queenList = nQueens.getQueenList();
        int score = 0;
        for (int i = 0; i < n; i++) {</pre>
            for (int j = i + 1; j < n; j++) {</pre>
                Queen leftQueen = queenList.get(i);
                Queen rightQueen = queenList.get(j);
                if (leftQueen.getRow() != null && rightQueen.getRow() != null) {
                     if (leftQueen.getRowIndex() == rightQueen.getRowIndex()) {
                         score--;
                     }
                     if (leftQueen.getAscendingDiagonalIndex() == rightQueen.getAscendingDiagona
                         score--;
                     }
                     if (leftQueen.getDescendingDiagonalIndex() == rightQueen.getDescendingDiago
                         score--;
                     }
                }
            }
        }
        return DefaultSimpleScore.valueOf(score);
    }
}
```

Configure it in your solver configuration:

```
<scoreDirectorFactory>
  <scoreDefinitionType>...</scoreDefinitionType>
```

ner.examples.nqueens.solver.score.NQueensSimpleScoreCalculator</

```
simpleScoreCalculatorClass>
  </scoreDirectorFactory>
```

Alternatively, build a simpleScoreCalculator instance at runtime and set it with the programmatic API:

solverFactory.getSolverConfig().getScoreDirectorFactoryConfig.setSimpleScoreCalculator(simpleScoreCalculator)

5.3.3. Incremental Java score calculation

A way to implement your score calculation incrementally in Java.

- · Advantages:
 - · Very fast and scalable
 - · Currently the fastest if implemented correctly
- Disadvantages:
 - · Hard to write
 - A scalable implementation heavily uses maps, indexes, ... (things the Drools rule engine can do for you)
 - · You have to learn, design, write and improve all these performance optimizations yourself
 - · Hard to read
 - Regular score constraint changes can lead to a high maintenance cost

Implement all the methods of the interface IncrementalScoreCalculator:

```
public interface IncrementalScoreCalculator<Sol extends Solution> {
    void resetWorkingSolution(Sol workingSolution);
    void beforeEntityAdded(Object entity);
    void afterEntityAdded(Object entity);
    void beforeAllVariablesChanged(Object entity);
    void afterAllVariablesChanged(Object entity);
    void beforeVariableChanged(Object entity, String variableName);
    void afterVariableChanged(Object entity, String variableName);
    void beforeEntityRemoved(Object entity);
    void afterEntityRemoved(Object entity);
    score calculateScore();
}
```

For example in n queens:

```
public class NQueensAdvancedIncrementalScoreCalculator extends AbstractIncrementalScoreCalculat
   private Map<Integer, List<Queen>> rowIndexMap;
   private Map<Integer, List<Queen>> ascendingDiagonalIndexMap;
   private Map<Integer, List<Queen>> descendingDiagonalIndexMap;
   private int score;
   public void resetWorkingSolution(NQueens nQueens) {
        int n = nQueens.getN();
       rowIndexMap = new HashMap<Integer, List<Queen>>(n);
        ascendingDiagonalIndexMap = new HashMap<Integer, List<Queen>>(n * 2);
       descendingDiagonalIndexMap = new HashMap<Integer, List<Queen>>(n * 2);
       for (int i = 0; i < n; i++) {</pre>
            rowIndexMap.put(i, new ArrayList<Queen>(n));
            ascendingDiagonalIndexMap.put(i, new ArrayList<Queen>(n));
            descendingDiagonalIndexMap.put(i, new ArrayList<Queen>(n));
            if (i != 0) {
             ascendingDiagonalIndexMap.put(n - 1 + i, new ArrayList<Queen>(n));
                descendingDiagonalIndexMap.put((-i), new ArrayList<Queen>(n));
            }
        }
        score = 0;
        for (Queen queen : nQueens.getQueenList()) {
            insert(queen);
        }
    }
   public void beforeEntityAdded(Object entity) {
       // Do nothing
   public void afterEntityAdded(Object entity) {
        insert((Queen) entity);
    }
   public void beforeAllVariablesChanged(Object entity) {
       retract((Queen) entity);
    }
   public void afterAllVariablesChanged(Object entity) {
       insert((Queen) entity);
    }
   public void beforeVariableChanged(Object entity, String variableName) {
       retract((Queen) entity);
```

```
public void afterVariableChanged(Object entity, String variableName) {
    insert((Queen) entity);
}
public void beforeEntityRemoved(Object entity) {
    retract((Queen) entity);
}
public void afterEntityRemoved(Object entity) {
    // Do nothing
}
private void insert(Queen queen) {
    Row row = queen.getRow();
    if (row != null) {
        int rowIndex = queen.getRowIndex();
        List<Queen> rowIndexList = rowIndexMap.get(rowIndex);
        score -= rowIndexList.size();
        rowIndexList.add(queen);
        List<Queen> ascendingDiagonalIndexList = ascendingDiagonalIndexMap.get(queen.getAsc
        score -= ascendingDiagonalIndexList.size();
        ascendingDiagonalIndexList.add(queen);
        List<Queen> descendingDiagonalIndexList = descendingDiagonalIndexMap.get(queen.get)
        score -= descendingDiagonalIndexList.size();
        descendingDiagonalIndexList.add(queen);
    }
}
private void retract(Queen queen) {
    Row row = queen.getRow();
    if (row != null) {
        List<Queen> rowIndexList = rowIndexMap.get(queen.getRowIndex());
        rowIndexList.remove(queen);
        score += rowIndexList.size();
        List<Queen> ascendingDiagonalIndexList = ascendingDiagonalIndexMap.get(queen.getAsc
        ascendingDiagonalIndexList.remove(queen);
        score += ascendingDiagonalIndexList.size();
        List<Queen> descendingDiagonalIndexList = descendingDiagonalIndexMap.get(queen.get)
        descendingDiagonalIndexList.remove(queen);
        score += descendingDiagonalIndexList.size();
    }
}
public SimpleScore calculateScore() {
    return DefaultSimpleScore.valueOf(score);
}
```

}

Configure it in your solver configuration:

```
<scoreDirectorFactory>
  <scoreDefinitionType>...</scoreDefinitionType>
```

re.NQueensAdvancedIncrementalScoreCalculator</

```
incrementalScoreCalculatorClass>
```

```
</scoreDirectorFactory>
```

5.3.4. Drools score calculation

5.3.4.1. Overview

Implement your score calculation using the Drools rule engine. Every score constraint is written as one or more score rules.

- Advantages:
 - · Incremental score calculation for free
 - Because most DRL syntax uses forward chaining, it does incremental calculation without any extra code
 - · Score constraints are isolated as separate rules
 - · Easy to add or edit existing score rules
 - · Flexibility to augment your score constraints by
 - · Defining them in decision tables
 - Excel (XLS) spreadsheet
 - Guvnor WebUI
 - · Translate them into natural language with DSL
 - · Store and release in the Guvnor repository
 - Performance optimizations in future versions for free
 - In every release, the Drools rule engine tends to become faster.
- Disadvantages:
 - DRL learning curve

- Usage of DRL
 - Polyglot fear can prohibit the use of a new language such as DRL in some organizations

5.3.4.2. Drools score rules configuration

There are sever ways to define where your score rules live.

5.3.4.2.1. A scoreDrl resource on the classpath

This is the easy way: the score rule live in a DRL file which is a resource on the classpath. Just add your score rules *.drl file in the solver configuration:

You can add multiple <scoreDrl> entries if needed, but normally you 'll define all your score rules in 1 file.

5.3.4.2.2. A RuleBase (possibly defined by Guvnor)

If you prefer to build the RuleBase yourself or if you're combining Planner with Guvnor, you can set the RuleBase on the SolverFactory before building the Solver:

solverFactory.getSolverConfig().getScoreDirectorFactoryConfig.setRuleBase(ruleBase);

5.3.4.3. Implementing a score rule

Here's an example of a score constraint implemented as a score rule in a DRL file:

This score rule will fire once for every 2 queens with the same $_{y}$. The (id > \$id) condition is needed to assure that for 2 queens A and B, it can only fire for (A, B) and not for (B, A), (A, A) or (B, B). Let's take a closer look at this score rule on this solution of 4 queens:

In this solution the multipleQueensHorizontal score rule will fire for 6 queen couples: (A, B), (A, C), (A, D), (B, C), (B, D) and (C, D). Because none of the queens are on the same vertical or diagonal line, this solution will have a score of -6. An optimal solution of 4 queens has a score of 0.

i

Note

Notice that every score rule will relate to at least 1 planning entity class (directly or indirectly though a logically inserted fact).

This is normal: it would be a waste of time to write a score rule that only relates to problem facts, as the consequence will never change during planning, no matter what the possible solution.

5.3.4.4. Aggregating the score rules into the score

A scoreHolder instance is asserted into the WorkingMemory as a global called scoreHolder. Your score rules need to (directly or indirectly) update that instance. Usually you 'll make a single rule as an aggregation of the other rules to update the score:

```
when
        $q1 : Queen($id : id, $ascendingD : ascendingD);
        $q2 : Queen(id > $id, ascendingD == $ascendingD);
    then
                                                               insertLogical(new
UnweightedConstraintOccurrence("multipleQueensAscendingDiagonal", $q1, $q2));
end
rule "multipleQueensDescendingDiagonal"
    when
        $q1 : Queen($id : id, $descendingD : descendingD);
        $q2 : Queen(id > $id, descendingD == $descendingD);
    then
                                                               insertLogical(new
UnweightedConstraintOccurrence("multipleQueensDescendingDiagonal", $q1, $q2));
end
rule "hardConstraintsBroken"
    when
        $occurrenceCount : Number() from accumulate(
            $unweightedConstraintOccurrence : UnweightedConstraintOccurrence(),
            count($unweightedConstraintOccurrence)
        );
    then
        scoreHolder.setScore(- $occurrenceCount.intValue());
end
```

Most use cases will also weigh their constraints differently, by multiplying the count of each score rule with its weight.

Here's an example from CurriculumCourse, where assigning a Lecture to a Room which is missing 2 seats is weighted equally bad as having 1 isolated Lecture in a Curriculum:

 $\ensuremath{{\prime\prime}}\xspace$ // CurriculumCompactness: Lectures belonging to a curriculum should be adjacent

```
// to each other (i.e., in consecutive periods).
// For a given curriculum we account for a violation every time there is one
lecture not adjacent
// to any other lecture within the same day.
// Each isolated lecture in a curriculum counts as 2 points of penalty.
rule "curriculumCompactness"
   when
        . . .
    then
            insertLogical(new IntConstraintOccurrence("curriculumCompactness",
ConstraintType.NEGATIVE_SOFT,
                2.
                ...));
end
// Accumulate soft constraints
rule "softConstraintsBroken"
        salience -1 // Do the other rules first (optional, for performance)
    when
        $softTotal : Number() from accumulate(
        IntConstraintOccurrence(constraintType == ConstraintType.NEGATIVE_SOFT,
 $weight : weight),
            sum($weight)
        )
    then
        scoreHolder.setSoftConstraintsBroken($softTotal.intValue());
end
```

5.4. Score calculation performance tricks

5.4.1. Overview

The solver will normally spend most of its execution time running the score calculation (which is called in its deepest loops). Faster score calculation will return the same solution in less time, which normally means a better solution in equal time.

After solving a problem, the solver will log the average calculation count per second. This is a good measurement of Score calculation performance, but it depends on the problem scale. Normally, even for high scale problems, it is higher than 1000, unless you're using SimpleScoreCalculator.

5.4.2. Incremental score calculation (with delta's)

When a solution changes, incremental score calculation (AKA delta based score calculation), will calculate the delta with the previous state to find the new score, instead of recalculating the entire score on every solution evaluation.

For example, if a single queen A moves from row 1 to 2, it won't bother to check if queen B and C can attack each other, since neither of them changed.

Figure 5.1. Incremental score calculation for the 4 queens puzzle

This is a huge performance and scalability gain. **Drools score calculation gives you this huge scalability gain without forcing you to write a complicated incremental score calculation algorithm.** Just let the Drools rule engine do the hard work.

Notice that the speedup is relative to the size of your planning problem (your *n*), making incremental score calculation far more scalable.

5.4.3. Caching

Do not call remote services in your score calculation (except if you're bridging simpleScoreCalculator to a legacy system). The network latency will kill your score calculation performance. Cache the results of those remote services if possible

If some parts of a constraint can be calculated once, when the solver starts, and never change during solving, then turn them into *cached problem facts*.

5.4.4. Unused constraint

If you know a certain constraint can never be broken, don't bother writing a score constraint for it. For example in n queens, the score calculation doesn't check if multiple queens occupy the

same column, because a Queen's column never changes and every Solution starts with each Queen on a different column.

Note

Don't go overboard with this. If some datasets don't use a specific constraint but others do, just return out of the constraint as soon as you can. There is no need to dynamically change your score calculation based on the dataset.

5.4.5. Build-in hard constraint

Instead of implementing a hard constraint, you can sometimes make it build-in too. For example: If Course A should never be assigned to Room X, but it uses ValueRange from Solution, the Solver will often try to assign it to Room X too (only to find out that it breaks a hard constraint). Switch to ValueRange from planning entity to define that Course A should only be assigned a Room other then X.

This tends to give a good performance gain, not just because the score calculation is faster, but mainly because most optimization algorithms will spend less time evaluating unfeasible solutions.

Note

Don't go overboard with this. Many optimization algorithms rely on the freedom to break hard constraints when changing planning entities, to get out of local optima. There is a risk of trading short term benefits for long term harm.

5.4.6. Other performance tricks

- Verify that your score calculation happens in the correct Number type. If you're making the sum of int values, don't let Drools sum it in a double which takes longer.
- For optimal performance, always use server mode (java -server). We have seen performance increases of 50% by turning on server mode.
- For optimal performance, use at least java 1.6. We have seen performance increases of 30% by switching from java 1.5 to 1.6.
- Always remember that premature optimization is the root of all evil. Make sure your design is flexible enough to allow configuration based tweaking.

5.4.7. Score trap

Be watchful for score traps. A score trap is a state in which several moves need to be done to resolve or lower the weight of a single constraint occurrence. Some examples of score traps:

- If you need 2 doctors at each table, but you're only moving 1 doctor at a time, then the solver has no incentive to move a doctor to a table with no doctors. Punish a table with no doctors more then a table with only 1 doctor in your score function.
- If you only add the table as a cause of the ConstraintOccurrence and forget the jobType (which is doctor or politician), then the solver has no incentive to move a doctor to table which is short of a doctor and a politician.

5.4.8. stepLimit benchmark

Not all score constraints have the same performance cost. Sometimes one score constraint can kill the score calculation performance outright. Use the benchmarker to do a 1 minute run and check what happens if you comment out all but a few of the score constraints.

5.5. Reusing the score calculation outside the Solver

Other parts of your application, for example your webUI, might need to calculate the score too. Do that by reusing the *scoreDirectorFactory* of the *solver* to build a separate *scoreDirector* for that webUI:

```
ScoreDirectorFactory scoreDirectorFactory = solver.getScoreDirectorFactory();
ScoreDirector guiScoreDirector = scoreDirectorFactory.buildScoreDirector();
```

Then use it when you need to calculate the score of a Solution:

```
guiScoreDirector.setWorkingSolution(solution);
Score score = guiScoreDirector.calculateScore();
```

Currently it's not officially supported to get the specific constraint occurrences, so you can explain in the GUI what entities are causing which part of the score. But if you're using the DroolsScoreDirector, it's possible. See the examples.

Chapter 6. Optimization algorithms

6.1. The size of real world problems

In number of possible solutions for a planning problem can be mind blowing. For example:

- 4 queens has 256 possible solutions (4 ^ 4) and 2 optimal solutions.
- 5 queens has 3125 possible solutions (5 ^ 5) and 1 optimal solution.
- 8 queens has 16777216 possible solutions (8 ^ 8) and 92 optimal solutions.
- 64 queens has more than 10^115 possible solutions (64 ^ 64).
- Most real-life planning problems have an incredible number of possible solutions and only 1 or a few optimal solutions.

For comparison: the minimal number of atoms in the known universe (10^80). As a planning problem gets bigger, the search space tends to blow up really fast. Adding only 1 extra planning entity or planning value can heavily multiply the running time of some algorithms.

An algorithm that checks every possible solution (even with pruning) can easily run for billions of years on a single real-life planning problem. What we really want is to **find the best solution in the limited time at our disposal**. Planning competitions (such as the International Timetabling Competition) show that local search variations (tabu search, simulated annealing, ...) usually perform best for real-world problems given real-world time limitations.

6.2. The secret sauce of Drools Planner

Drools Planner is the first framework to combine optimization algorithms (metaheuristics, ...) with score calculation by a rule engine such as Drools Expert. This combination turns out to be a very efficient, because:

- A rule engine such as Drools Expert is **great for calculating the score** of a solution of a planning problem. It make it easy and scalable to add additional soft or hard constraints such as "a teacher shouldn't teach more then 7 hours a day". It does delta based score calculation without any extra code. However it tends to be not suited to use to actually find new solutions.
- An optimization algorithm is **great at finding new improving solutions** for a planning problem, without necessarily brute-forcing every possibility. However it needs to know the score of a solution and offers no support in calculating that score efficiently.

6.3. Optimization algorithms overview

Algorithm	Scalable?	Optimal solution?	Needs little configuration?		Requires initialized solution?
Exact algorithms					
Brute force	0/5	5/5 - Guaranteed	5/5	0/5	No
Branch and bound	0/5	5/5 - Guaranteed	4/5	1/5	No
Construction heuristics					
First Fit	5/5	1/5 - Stops after initialization	5/5	1/5	No
First Fit Decreasing	5/5	2/5 - Stops after initialization	4/5	2/5	No
Best Fit	5/5	2/5 - Stops after initialization	4/5	2/5	No
Best Fit Decreasing	5/5	2/5 - Stops after initialization	4/5	2/5	No
Cheapest Insertion	3/5	2/5 - Stops after initialization	5/5	2/5	No
Metaheuristic	S				
Local search					
Hill- climbing	4/5	2/5 - Gets stuck in local optima	3/5	3/5	Yes
Tabu search	4/5	4/5	3/5	5/5	Yes
Simulated annealing	4/5	4/5	2/5	5/5	Yes

Algorithm	Scalable?	Optimal solution?	Needs little configuration?	Highly configurable?	Requires initialized solution?
Evolutionary algorithms					
Evolutionary strategies	4/5	?/5	?/5	?/5	Yes
Genetic algorithms	4/5	?/5	?/5	?/5	Yes

If you want to learn more about metaheuristics, read the free book *Essentials* of *Metaheuristics* [http://www.cs.gmu.edu/~sean/book/metaheuristics/] or *Clever Algorithms* [http:// www.cleveralgorithms.com/].

6.4. Which optimization algorithms should I use?

The *best* optimization algorithms configuration for your use case depends heavily on your use case. Nevertheless, this vanilla recipe will get you into the game with a pretty good configuration, probably much better than what you're used to.

Start with a quick configuration that involves little or no configuration and optimization code:

1. First Fit

Next, implement planning entity difficulty comparison and turn it into:

1. First Fit Decreasing

Next, implement moves and add tabu search behind it:

- 1. First Fit Decreasing
- 2. Tabu search (use planning entity tabu)

At this point *the free lunch is over*. The return on invested time lowers. The result is probably already more than good enough.

But you can do even better, at a lower return on invested time. Use the Benchmarker and try a couple of simulated annealing configurations:

- 1. First Fit Decreasing
- 2. Simulated annealing (try several starting temperatures)

And combine them with tabu search:

1. First Fit Decreasing

- 2. Simulated annealing (relatively long time)
- 3. Tabu search (relatively short time)

If you have time, continue experimenting even further. Blog about your experiments!

6.5. SolverPhase

A solver can use multiple optimization algorithms in sequence. Each optimization algorithm is represented by a solverPhase. There is never more than 1 SolverPhase solving at the same time.

Note

Some SolverPhase implementations can combine techniques from multiple optimization algorithms, but they are still just 1 SolverPhase. For example: a local search SolverPhase can do simulated annealing with planning entity tabu.

Here's a configuration that runs 3 phases in sequence:

```
<solver>
...
<constructionHeuristic>
... <!-- First phase: First Fit decreasing -->
</constructionHeuristic>
<localSearch>
... <!-- Second phase: Simulated annealing -->
</localSearch>
<localSearch>
... <!-- Third phase: Tabu search -->
</localSearch>
</solver>
```

The solver phases are run in the order defined by solver configuration. When the first phase terminates, the second phase starts, and so on. When the last phase terminates, the solver terminates.

Some phases (especially construction heuristics) will terminate automatically. Other phases (especially metaheuristics) will only terminate if the phase is configured to terminate:

If the solver terminates (before the last phase terminates itself), the current phase is terminated and all subsequent phases won't run.

6.6. Termination

Not all phases terminate automatically and sometimes you don't want to wait that long anyway. A solver can be terminated synchronously by up-front configuration or asynchronously from another thread.

Especially metaheuristics phases will need to be told when to stop solving. This can be because of a number of reasons: the time is up, the perfect score has been reached, ... The only thing you can't depend on is on finding the optimal solution (unless you know the optimal score), because a metaheuristics algorithm generally doesn't know it when it finds the optimal solution. For real-life problems this doesn't turn out to be much of a problem, because finding the optimal solution could take billions of years, so you 'll want to terminate sooner anyway. The only thing that matters is finding the best solution in the available time.

For synchronous termination, configure a Termination on a Solver or a SolverPhase when it needs to stop. You can implement your own Termination, but the build-in implementations should suffice for most needs. Every Termination can calculate a *time gradient* (needed for some optimization algorithms), which is a ratio between the time already spend solving and the estimated entire solving time of the Solver or SolverPhase.

6.6.1. TimeMillisSpendTermination

Terminates when an amount of time has been reached:

```
<termination>
<maximumTimeMillisSpend>500</maximumTimeMillisSpend>
</termination>
```

<termination>

```
<maximumSecondsSpend>10</maximumSecondsSpend> </termination>
```

<termination>

- <maximumMinutesSpend>5</maximumMinutesSpend>
- </termination>

```
<termination>
<maximumHoursSpend>1</maximumHoursSpend>
</termination>
```

Note

If you use this Termination, you will most likely sacrifice perfect reproducibility (even with environmentMode REPRODUCIBLE) because of an available CPU time difference:

- The available CPU time influences the number of steps that can be taken, which might be a few more or less.
- The Termination might produce slightly different time gradient values, which will send time gradient based algorithms (such as simulated annealing) on a radically different path.

6.6.2. ScoreAttainedTermination

Terminates when a certain score has been reached. You can use this Termination if you know the perfect score, for example for 4 queens:

```
<termination>
<scoreAttained>0</scoreAttained>
</termination>
```

For a planning problem with hard and soft constraints, it could look like this:

```
<termination>
<scoreAttained>Ohard/-5000soft</scoreAttained>
</termination>
```

You can use this Termination to terminate once it reaches a feasible solution.

6.6.3. StepCountTermination

Terminates when an amount of steps has been reached:

```
<termination>
        <maximumStepCount>100</maximumStepCount>
</termination>
```

This Termination can only be used for a SolverPhase, not for the Solver itself.

6.6.4. UnimprovedStepCountTermination

Terminates when the best score hasn't improved in a number of steps:

```
<termination>
<maximumUnimprovedStepCount>100</maximumUnimprovedStepCount>
</termination>
```

If it hasn't improved recently, it's probably not going to improve soon anyway and it's not worth the effort to continue. We have observed that once a new best solution is found (even after a long time of no improvement on the best solution), the next few step tend to improve the best solution too.

This Termination can only be used for a SolverPhase, not for the Solver itself.

6.6.5. Combining Terminations

Terminations can be combined, for example: terminate after 100 steps or if a score of 0 has been reached:

```
<termination>
<terminationCompositionStyle>OR</terminationCompositionStyle>
<maximumStepCount>100</maximumStepCount>
<scoreAttained>0</scoreAttained>
</termination>
```

Alternatively you can use AND, for example: terminate after reaching a feasible score of at least -100 and no improvements in 5 steps:

```
<termination>
<terminationCompositionStyle>AND</terminationCompositionStyle>
<maximumUnimprovedStepCount>5</maximumUnimprovedStepCount>
```

```
<scoreAttained>-100</scoreAttained>
</termination>
```

This example ensures it doesn't just terminate after finding a feasible solution, but also completes any obvious improvements on that solution before terminating.

6.6.6. Asynchronous termination from another thread

Sometimes you 'll want to terminate a Solver early from another thread, for example because a user action or a server restart. That cannot be configured by a Termination as it's impossible to predict when and if it will occur. Therefor the solver interface has these 2 thread-safe methods:

```
public interface Solver {
    // ...
    boolean terminateEarly();
    boolean isTerminateEarly();
}
```

If you call the terminateEarly() method from another thread, the solver will terminate at its earliest convenience and the solve() method will return in the original Solver thread.

6.7. SolverEventListener

Each time a new best solution is found, the Solver fires a BestSolutionChangedEvent.

To listen to such events, add a SolverEventListener to the Solver:

```
public interface Solver {
    // ...
    void addEventListener(SolverEventListener eventListener);
    void removeEventListener(SolverEventListener eventListener);
}
```

6.8. Custom SolverPhase

Between phases or before the first phase, you might want to execute a custom action on the solution to get a better score. Yet you'll still want to reuse the score calculation. For example, to implement a custom construction heuristic without implementing an entire solverPhase.

Note

Most of the time, a custom construction heuristic is not worth the hassle. The supported constructions heuristics are configurable (so you can tweak them with the Benchmarker), Termination aware and support partially initialized solutions too.

Implement the CustomSolverPhaseCommand interface:

```
public interface CustomSolverPhaseCommand {
    void changeWorkingSolution(ScoreDirector scoreDirector);
}
```

For example:

```
public class ExaminationSolutionInitializer implements CustomSolverPhaseCommand {
    public void changeWorkingSolution(ScoreDirector scoreDirector) {
        Examination examination = (Examination) scoreDirector.getWorkingSolution();
        for (Exam exam : examination.getExamList()) {
            Score unscheduledScore = scoreDirector.calculateScore();
            . . .
            for (Period period : examination.getPeriodList()) {
                scoreDirector.beforeVariableChanged(exam, "period");
                exam.setPeriod(period)
                scoreDirector.afterVariableChanged(exam, "period");
                Score score = scoreDirector.calculateScore();
                . . .
            }
            . . .
        }
    }
}
```

Warning

Any change on the planning entities in a CustomSolverPhaseCommand must be notified to the ScoreDirector.

Warning

Do not change any of the planning facts in a CustomSolverPhaseCommand. That will corrupt the Solver because any previous score or solution was for a different problem. If you want to do that, see *repeated planning* and real-time planning instead.

And configure it like this:

```
</solver>
```

It's possible to configure multiple customSolverPhaseCommandClass instances, which will be run in sequence.

Note

If the changes of a CustomSolverPhaseCommand don't result in a better score, the best solution won't be changed (so effectively nothing will have changed for the next SolverPhase or CustomSolverPhaseCommand). TODO: we might want to change this behaviour?

Note

If the Solver or SolverPhase wants to terminate while a CustomSolverPhaseCommand is still running, it will wait to terminate until the CustomSolverPhaseCommand is done.

Chapter 7. Exact methods

7.1. Overview

Exact methods will always find the global optimum and recognize it too. That being said, they don't scale (not even beyond toy problems) and are therefor mostly useless.

7.2. Brute Force

7.2.1. Algorithm description

The brute force algorithm creates and evaluates every possible solution.

Notice that it creates a search tree that explodes as the problem size increases. Brute force is mostly unusable for a real-world problem due to time limitations.

7.2.2. Configuration

Using the brute force algorithm is easy:

<solver></solver>
<bruteforce></bruteforce>

7.3. Branch and bound

7.3.1. Algorithm description

Branch and bound is an improvement over brute force, as it prunes away subsets of solutions which cannot have a better solution than the best solution already found at that point.

Notice that it (like brute force) creates a search tree that explodes (but less than brute force) as the problem size increases. Branch and bound is mostly unusable for a real-world problem due to time limitations.

It can determine a *lower bound* of problem. A lower bound is a score which is proven to be higher than the optimal score of a problem. So it gives an indication of the quality of any best solution found for that problem: the closer to best score is to the lower bound, the better.

7.3.2. Configuration

Branch and bound is not yet implemented in Drools Planner. Patches welcome.

Chapter 8. Construction heuristics

8.1. Overview

A construction heuristic builds a pretty good initial solution in a finite length of time. Its solution isn't always feasible, but it finds it fast and metaheuristics can finish the job.

Construction heuristics terminate automatically, so there's usually no need to configure a Termination on the construction heuristic phase specifically.

8.2. First Fit

8.2.1. Algorithm description

The *First Fit* algorithm cycles through all the planning entity (in default order), initializing 1 planning entity at a time. It assigns the planning entity to the best available planning value, taking the already initialized planning entities into account. It terminates when all planning entities have been initialized. It never changes a planning entity after it has been assigned.

Notice that it starts with putting Queen A into row 0 (and never moving it later), which makes it impossible reach the optimal solution. Suffixing this construction heuristic with metaheurstics can remedy that.

8.2.2. Configuration

Configure this SolverPhase:

```
<constructionHeuristic>
   <constructionHeuristicType>FIRST_FIT</constructionHeuristicType>
   <!-- Speedup that can be applied to most, but not all use cases: -->
   <!--
constructionHeuristicPickEarlyType> -->
   </constructionHeuristic>
```

Note

The constructionHeuristicPickEarlyType of FIRST_LAST_STEP_SCORE_EQUAL_OR_IMPROVING is a big speedup, which should be applied when initializing a planning entity can only make the score lower or equal. So if:

- There are no positive constraints.
- There is no negative constraint that can stop been broken by adding a planning entity (except if another negative constraint gets broken which outweighs it the first negative constraint).

If that is not the case, then it can still be good to apply it in some cases, but not in most cases. Use the Benchmarker to decide.

8.3. First Fit Decreasing

8.3.1. Algorithm description

Like First Fit, but assigns the more difficult planning entities first, because they are less likely to fit in the leftovers. So it sorts the planning entities on decreasing difficulty.

Requires the model to support *planning entity difficulty comparison*.

Note

One would expect that this algorithm always performs better than First Fit. That's not always the case, but usually is.

8.3.2. Configuration

Configure this SolverPhase:

```
<constructionHeuristic>
<constructionHeuristicType>FIRST_FIT_DECREASING</constructionHeuristicType>
<!-- Speedup that can be applied to most, but not all use cases: -->
<!--
constructionHeuristicPickEarlyType> -->
</constructionHeuristic>
```

8.4. Best Fit

8.4.1. Algorithm description

Like First Fit, but uses the weaker planning values first, because the strong planning values are more likely to be able to accommodate later planning entities. So it sorts the planning values on increasing strength.

Requires the model to support *planning value strength comparison*.

8.4.2. Configuration

Configure this SolverPhase:

```
<constructionHeuristic>
   <constructionHeuristicType>BEST_FIT</constructionHeuristicType>
   <!-- Speedup that can be applied to most, but not all use cases: -->
   <!--
constructionHeuristicPickEarlyType> -->
   </constructionHeuristic>
```

8.5. Best Fit Decreasing

8.5.1. Algorithm description

Combines First Fit Decreasing and Best Fit. So it sorts the planning entities on decreasing difficulty and the planning values on increasing strength.

Requires the model to support *planning entity difficulty comparison* and *planning value strength comparison*.

Note

One would expect that this algorithm always performs better than First Fit, First Fit Decreasing and Best Fit. That's not always the case.

8.5.2. Configuration

Configure this SolverPhase:

8.6. Cheapest insertion

8.6.1. Algorithm description

TODO

8.6.2. Configuration

TODO Not implemented yet.
Chapter 9. Local search

9.1. Overview

Local search starts from an initial solution and evolves that single solution into a mostly better and better solution. It uses a single search path of solutions, not a search tree. At each solution in this path it evaluates a number of moves on the solution and applies the most suitable move to take the step to the next solution. It does that for high number of iterations until its terminated (usually because its time has run out).

Local search acts a lot like a human planner: it uses a single search path and moves facts around to find a good feasible solution. Therefore it's pretty natural to implement.

Local search needs to start from an initialized solution, therefor it's recommended to configure a construction heuristic solver phase before it.

9.2. Hill climbing (simple local search)

9.2.1. Algorithm description

Hill climbing can easily get stuck in a local optima, but improvements (such as tabu search and simulated annealing) address this problem.

9.3. Tabu search

9.3.1. Algorithm description

Like hill climbing, but maintains a tabu list to avoid getting stuck in local optima. See Tabu Search acceptor below.

9.4. Simulated annealing

9.4.1. Algorithm description

See Simulated Annealing acceptor below.

9.5. About neighborhoods, moves and steps

9.5.1. A move

A move is the change from a solution A to a solution B. For example, below you can see a single move on the starting solution of 4 queens that moves a single queen to another row:

	А	в	С	D		А	в	С	D
0	Ŵ	З Ш	Ŵ	Ŵ	0	Ŵ	W		Ŵ
1					1				
2			6		2			Ŵ	
З					3				

Figure 9.1. A single move (4 queens example)

A move can have a small or large impact. In the above example, the move of queen C0 to C2 is a small move. Some moves are the same move type. These are some possibilities for move types in n queens:

- Move a single queen to another row. This is a small move. For example, move queen C0 to C2.
- Move all queens a number of rows down or up. This a big move.
- Move a single queen to another column. This is a small move. For example, move queen C2 to A0 (placing it on top of queen A0).
- Add a queen to the board at a certain row and column.
- Remove a queen from the board.

Because we have decided that all queens will be on the board at all times and each queen has an appointed column (for performance reasons), only the first 2 move types are usable in our example. Furthermore, we 're only using the first move type in the example because we think it gives the best performance, but you are welcome to prove us wrong.

Each of your move types will be an implementation of the Move interface:

```
public interface Move {
    boolean isMoveDoable(ScoreDirector scoreDirector);
    Move createUndoMove(ScoreDirector scoreDirector);
    void doMove(ScoreDirector scoreDirector);
}
```

Let's take a look at the Move implementation for 4 queens which moves a queen to a different row:

public class RowChangeMove implements Move {

```
private Queen queen;
private Row toRow;
public RowChangeMove(Queen queen, Row toRow) {
    this.queen = queen;
    this.toRow = toRow;
}
// ... see below
}
```

An instance of RowChangeMove moves a queen from its current row to a different row.

Planner calls the doMove(ScoreDirector) method to do a move. The Move implementation must notify the ScoreDirector of any changes it make to the planning entities's variables:

```
public void doMove(ScoreDirector scoreDirector) {
    scoreDirector.beforeVariableChanged(queen, "row"); // before changes
are made
    queen.setRow(toRow);
    scoreDirector.afterVariableChanged(queen, "row"); // after changes are made
    }
```

You need to call the methods scoreDirector.beforeVariableChanged(Object, scoreDirector.afterVariableChanged(Object, and before String) String) after and modifying the entity. Alternatively, also you can call the methods scoreDirector.beforeAllVariablesChanged(Object) and scoreDirector.afterAllVariablesChanged(Object).

Note

You can alter multiple entities in a single move and effectively create a big move (also known as a coarse-grained move). A move cannot change any of the problem facts.

Planner automatically filters out *non doable moves* by calling the isDoable(ScoreDirector) method on a move. A *non doable move* is:

- A move that changes nothing on the current solution. For example, moving queen B0 to row 0 is not doable, because it is already there.
- A move that is impossible to do on the current solution. For example, moving queen B0 to row 10 is not doable because it would move it outside the board limits.

In the n queens example, a move which moves the queen from its current row to the same row isn't doable:

```
public boolean isMoveDoable(ScoreDirector scoreDirector) {
    return !ObjectUtils.equals(queen.getRow(), toRow);
}
```

Because we won't generate a move which can move a queen outside the board limits, we don't need to check it. A move that is currently not doable could become doable on the working solution of a later step.

Each move has an *undo move*: a move (normally of the same type) which does the exact opposite. In the example above the undo move of *C0 to C2* would be the move *C2 to C0*. An undo move is created from a Move, before the Move has been done on the current solution.

```
public Move createUndoMove(ScoreDirector scoreDirector) {
    return new RowChangeMove(queen, queen.getRow());
}
```

Notice that if C0 would have already been moved to C2, the undo move would create the move *C2 to C2*, instead of the move *C2 to C0*.

The local search solver phase might do and undo the same Move more than once, even on different (successive) solutions.

A Move must implement the getPlanningEntities() and getPlanningValues() methods. They are used by entity tabu and value tabu respectively. When they are called, the Move has already been done.

```
public List<? extends Object> getPlanningEntities() {
    return Collections.singletonList(queen);
}
public Collection<? extends Object> getPlanningValues() {
    return Collections.singletonList(toRow);
}
```

If your Move changes multiple planning entities, return all them in getPlanningEntities() and return all their values (to which they are changing) in getPlanningValues().

```
public Collection<? extends Object> getPlanningEntities() {
    return Arrays.asList(leftCloudProcess, rightCloudProcess);
}
```

```
public Collection<? extends Object> getPlanningValues() {
    return Arrays.asList(leftCloudProcess.getComputer(), rightCloudProcess.getComputer());
}
```

A Move must implement the equals() and hashCode() methods. 2 moves which make the same change on a solution, should be equal.

```
public boolean equals(Object o) {
    if (this == 0) {
        return true;
    } else if (o instanceof RowChangeMove) {
        RowChangeMove other = (RowChangeMove) o;
        return new EqualsBuilder()
                .append(queen, other.queen)
                 .append(toRow, other.toRow)
                .isEquals();
    } else {
        return false;
    }
}
public int hashCode() {
    return new HashCodeBuilder()
            .append(queen)
            .append(toRow)
            .toHashCode();
}
```

In the above example, the <code>Queen</code> class uses the default <code>Object equals()</code> and <code>hashCode()</code> implementations. Notice that it checks if the other move is an instance of the same move type. This <code>instanceof</code> check is important because a move will be compared to a move with another move type if you're using more then 1 move type.

It's also recommended to implement the tostring() method as it allows you to read Planner's logging more easily:

```
public String toString() {
    return queen + " => " + toRow;
}
```

Now that we can make a single move, let's take a look at generating moves.

9.5.2. Move generation

At each solution, local search will try all possible moves and pick the best move to change to the next solution. It's up to you to generate those moves. Let's take a look at all the possible moves on the starting solution of 4 queens:

Figure 9.2. Possible moves at step 0 (4 queens example)

As you can see, not all the moves are doable. At the starting solution we have 12 doable moves (n * (n - 1)), one of which will be move which changes the starting solution into the next solution. Notice that the number of possible solutions is 256 $(n ^ n)$, much more that the amount of doable moves. Don't create a move to every possible solution. Instead use moves which can be sequentially combined to reach every possible solution.

It's highly recommended that you verify all solutions are connected by your move set. This means that by combining a finite number of moves you can reach any solution from any solution. Otherwise you're already excluding solutions at the start. Especially if you're using only big moves, you should check it. Just because big moves outperform small moves in a short test run, it doesn't mean that they will outperform them in a long test run.

You can mix different move types. Usually you're better off preferring small (fine-grained) moves over big (course-grained) moves because the score delta calculation will pay off more. However, as the traveling tournament example proves, if you can remove a hard constraint by using a certain set of big moves, you can win performance and scalability. Try it yourself: run both the simple (small moves) and the smart (big moves) version of the traveling tournament example. The smart version evaluates a lot less unfeasible solutions, which enables it to outperform and outscale the simple version.

Move generation currently happens with a MoveFactory:

```
public class RowChangeMoveFactory extends CachedMoveListMoveFactory {
    public List<Move> createMoveList(Solution solution) {
```

```
NQueens nQueens = (NQueens) solution;
List<Move> moveList = new ArrayList<Move>();
for (Queen queen : nQueens.getQueenList()) {
    for (Row toRow : nQueens.getRowList()) {
        moveList.add(new RowChangeMove(queen, toRow));
    }
    }
    return moveList;
}
```

Future versions might also support move generation by DRL.

9.5.3. Generic MoveFactory

To get started quickly, Planner comes with a few build-in MoveFactory implementations:

- GenericChangeMoveFactory: A GenericChangeMove changes 1 planning variable of 1 planning entity to another planning value. For example: Given course C1 in room R1 and period P1, change its room to room R2.
- GenericSwapMoveFactory: A GenericSwapMove swaps all the planning variables of 2 planning entities. For example: Given course C1 in room R1 and period P1 and course C2 in room R2 and period P2, put course C1 in room R2 and period P2 and put course C2 in room R1 and period P1.
- GenericSwapPillarMoveFactory: A GenericSwapPillarMove swaps all the planning variables of 2 pillars. A pillar is a set of planning entities that have the same planning values for all those planning variables. For example: Given course C10, course 11 and course 12 in room R1 and period P1 and course C20 in room R2 and period P2, put course C10, course 11 and course 12 in room R2 and period P2 and put course C20 in room R1 and period P1.

To use one or multiple build-in MoveFactory implementations, configure it as a Selector:

```
<localSearch>
    <selector>
        <selector>
        <selectoryClass>org.drools.planner.core.move.generic.GenericChangeMoveFactory</
        moveFactoryClass>
        </selector>
        <selector>
        <moveFactoryClass>org.drools.planner.core.move.generic.GenericSwapMoveFactory</moveFactoryClass>
```

```
</selector>
</selector>
...
</localSearch>
```

They are slightly slower than a custom implementation, but equally scalable.

9.5.4. A step

A step is the winning move. The local search solver tries every move on the current solution and picks the best accepted move as the step:

Figure 9.3. Decide the next step at step 0 (4 queens example)

Because the move *B0 to B3* has the highest score (-3), it is picked as the next step. Notice that *C0 to C3* (not shown) could also have been picked because it also has the score -3. If multiple moves have the same highest score, one is picked randomly, in this case *B0 to B3*.

The step is made and from that new solution, the local search solver tries all the possible moves again, to decide the next step after that. It continually does this in a loop, and we get something like this:

Figure 9.4. All steps (4 queens example)

Notice that the local search solver doesn't use a search tree, but a search path. The search path is highlighted by the green arrows. At each step it tries all possible moves, but unless it's the step, it doesn't investigate that solution further. This is one of the reasons why local search is very scalable.

As you can see, the local search solver solves the 4 queens problem by starting with the starting solution and make the following steps sequentially:

1. B0 to B3

2. D0 to B2

3. A0 to B1

If we turn on DEBUG logging for the category org.drools.planner, then those steps are shown into the log:

INFO Solving started: time spend (0), score (-6), new best score (-6), random seed (0). DEBUG Step index (0), time spend (20), score (-3), new best score (-3), accepted move size (12) for picked step (coll@row0 => row3). DEBUG Step index (1), time spend (31), score (-1), new best score (-1), accepted move size (12) for picked step (coll@row0 => row1). DEBUG Step index (2), time spend (40), score (0), new best score (0), accepted move size (12) for picked step (coll@row0 => row2). INFO Phase localSearch ended: step total (3), time spend (41), best score (0). INFO Solving ended: time spend (41), best score (0), average calculate count per second (1780).

Notice that the logging uses the toString() method of our Move implementation: coll@row0 => row3.

The local search solver solves the 4 queens problem in 3 steps, by evaluating only 37 possible solutions (3 steps with 12 moves each + 1 starting solution), which is only fraction of all 256 possible solutions. It solves 16 queens in 31 steps, by evaluating only 7441 out of 18446744073709551616 possible solutions. Note: with construction heuristics it's even a lot more efficient.

9.5.5. Getting stuck in local optima

A *hill climber* always takes improving moves. This may seem like a good thing, but it's not. It suffers from a number of problems:

- It can get stuck in a local optimum. For example if it reaches a solution X with a score -1 and there is no improving move, it is forced to take a next step that leads to a solution Y with score -2, after that however, it's very real that it will pick the step back to solution X with score -1. It will then start looping between solution X and Y.
- It can start walking in its own footsteps, picking the same next step at every step.

Of course Drools Planner implements better local searches, such as *tabu search* and *simulated annealing* which can avoid these problems. We recommend to never use a hill climber, unless you're absolutely sure there are no local optima in your planning problem.

9.6. Deciding the next step

The local search solver decides the next step with the aid of 3 configurable components:

- A selector which selects (or generates) the possible moves of the current solution.
- An acceptor which filters out unacceptable moves. It can also weigh a move it accepts.
- A forager which gathers all accepted moves and picks the next step from them.

Figure 9.5. Decide the next step at step 0 (4 queens example)

In the above example the selector generated the moves shown with the blue lines, the acceptor accepted all of them and the forager picked the move *B0 to B3*.

If we turn on TRACE logging for the category org.drools.planner, then the decision making is shown in the log:

```
INFO Solver started: time spend (0), score (-6), new best score (-6), random
seed (0).
TRACE Ignoring not doable move (col0@row0 => row0).
TRACE Move score (-4), accepted (true) for move (col0@row0 => row1).
```

```
TRACE
              Move score (-4), accepted (true) for move (col0@row0 => row2).
              Move score (-4), accepted (true) for move (col0@row0 => row3).
TRACE
. . .
              Move score (-3), accepted (true) for move (coll@row0 => row3).
TRACE
. . .
TRACE
              Move score (-3), accepted (true) for move (col2@row0 => row3).
. . .
              Move score (-4), accepted (true) for move (col3@row0 => row3).
TRACE
DEBUG
           Step index (0), time spend (6), score (-3), new best score (-3),
accepted move size (12) for picked step (coll@row0 => row3).
. . .
```

Because the last solution can degrade (especially in tabu search and simulated annealing), the solver remembers the best solution it has encountered through the entire search path. Each time the current solution is better than the last best solution, the current solution is cloned and referenced as the new best solution.

9.6.1. Selector

A selector is currently based on a MoveFactory.

```
<selector>
<moveFactoryClass>org.drools.planner.examples.nqueens.solver.NQueensMoveFactory</
moveFactoryClass>
    </selector>
```

You're not obligated to generate the same set of moves at each step. It's generally a good idea to use several selectors, mixing fine grained moves and course grained moves:

```
<selector>
.nurserostering.solver.move.factory.EmployeeChangeMoveFactory</
moveFactoryClass>
</selector>
ering.solver.move.factory.ShiftAssignmentSwapMoveFactory</
moveFactoryClass>
</selector>
ctory.ShiftAssignmentPillarPartSwapMoveFactory</
moveFactoryClass>
```

</selector>

9.6.2. Acceptor

An acceptor is used (together with a forager) to active tabu search, simulated annealing, great deluge, ... For each move it checks whether it is accepted or not.

You can implement your own Acceptor, although the build-in acceptors should suffice for most needs. You can also combine multiple acceptors.

9.6.2.1. Tabu search acceptor

When tabu search takes steps it creates tabu's. It does not accept a move as the next step if that move breaks tabu. Drools Planner implements several tabu types:

• Solution tabu makes recently visited solutions tabu. It does not accept a move that leads to one of those solutions. If you can spare the memory, don't be cheap on the tabu size.

```
<acceptor>
    <solutionTabuSize>1000</solutionTabuSize>
</acceptor>
```

• Move tabu makes recent steps tabu. It does not accept a move equal to one of those steps.

```
<acceptor>
    <moveTabuSize>7</moveTabuSize>
</acceptor>
```

• Undo move tabu makes the undo move of recent steps tabu.

```
<acceptor>
    <ur>
        <ur>
            <undoMoveTabuSize>7</undoMoveTabuSize></acceptor>
        </ur>
    </ur>
```

• *Planning entity tabu* makes the planning entities of recent steps tabu. For example, for N queens it makes the recently moved queens tabu.

```
<acceptor>
    <planningEntityTabuSize>7</planningEntityTabuSize>
```

</acceptor>

• *Planning value tabu* makes the planning values of recent steps tabu. For example, for N queens it makes the recently moved to rows tabu.

```
<acceptor>
    <planningValueTabuSize>7</planningValueTabuSize>
</acceptor>
```

You can even combine tabu types:

```
<acceptor>
    <solutionTabuSize>1000</solutionTabuSize>
    <moveTabuSize>7</moveTabuSize>
</acceptor>
```

If you pick a too small tabu size, your solver can still get stuck in a local optimum. On the other hand, with the exception of solution tabu, if you pick a too large tabu size, your solver can get stuck by bouncing of the walls. Use the benchmarker to fine tweak your configuration. Experiments teach us that it is generally best to use a prime number for the move tabu, undo move tabu, entity tabu or value tabu size.

A tabu search acceptor should be combined with a high subset selection, such as 1000.

9.6.2.2. Simulated annealing acceptor

Simulated annealing does not always pick the move with the highest score, neither does it evaluate many moves per step. At least at first. Instead, it gives non improving moves also a chance to be picked, depending on its score and the time gradient of the Termination. In the end, it gradually turns into a hill climber, only accepting improving moves.

In many use cases, simulated annealing surpasses tabu search. By changing a few lines of configuration, you can easily switch from tabu search to simulated annealing and back.

Start with a simulatedAnnealingStartingTemperature set to the maximum score delta a single move can cause. Use the Benchmarker to tweak the value.

```
<acceptor>
        <simulatedAnnealingStartingTemperature>2hard/100soft</
simulatedAnnealingStartingTemperature>
        </acceptor>
        <forager>
            <minimalAcceptedSelection>4</minimalAcceptedSelection>
```

</forager>

A simulated annealing acceptor should be combined with a low subset selection. The classic algorithm uses a minimalAcceptedSelection of 1, but usually 4 performs better.

You can even combine it with a tabu acceptor at the same time. Use a lower tabu size than in a pure tabu search configuration.

```
<acceptor>

<simulatedAnnealingStartingTemperature>10.0</
simulatedAnnealingStartingTemperature>
<planningEntityTabuSize>5</planningEntityTabuSize>
</acceptor>
<forager>
<minimalAcceptedSelection>4</minimalAcceptedSelection>
</forager>
```

This differs from phasing, another powerful technique, where first simulated annealing is used, followed by tabu search.

9.6.3. Forager

A forager gathers all accepted moves and picks the move which is the next step. Normally it picks the accepted move with the highest score. If several accepted moves have the highest score, one is picked randomly.

You can implement your own Forager, although the build-in forager should suffice for most needs.

9.6.3.1. Subset selection

When there are many possible moves, it becomes inefficient to evaluate all of them at every step. To evaluate only a random subset of all the moves, use:

• An minimalAcceptedSelection integer, which specifies how many accepted moves should have be evaluated during each step. By default it is positive infinity, so all accepted moves are evaluated at every step.

```
<forager>
    <minimalAcceptedSelection>1000</minimalAcceptedSelection>
</forager>
```

Unlike the n queens problem, real world problems require the use of subset selection. Start from an minimalAcceptedSelection that takes a step in less then 2 seconds. Turn on INFO logging to see the step times. Use the Benchmarker to tweak the value.

9.6.3.2. Pick early type

A forager can pick a move early during a step, ignoring subsequent selected moves. There are 3 pick early types:

• NEVER: A move is never picked early: all accepted moves are evaluated that the selection allows. This is the default.

```
<forager>
<pickEarlyType>NEVER</pickEarlyType>
</forager>
```

• FIRST_BEST_SCORE_IMPROVING: Pick the first accepted move that improves the best score. If none improve the best score, it behaves exactly like the pickEarlyType NEVER.

```
<forager>
    <pickEarlyType>FIRST_BEST_SCORE_IMPROVING</pickEarlyType>
</forager>
```

• FIRST_LAST_STEP_SCORE_IMPROVING: Pick the first accepted move that improves the last step score. If none improve the last step score, it behaves exactly like the pickEarlyType NEVER.

```
<forager>
    <pickEarlyType>FIRST_LAST_STEP_SCORE_IMPROVING</pickEarlyType>
</forager>
```

9.7. Using a custom Selector, Acceptor, Forager or Termination

You can plug in a custom Selector, Acceptor, Forager or Termination by extending the abstract class and also the *Config class.

For example, to use a custom Selector, extend the AbstractSelector class (see AllMovesOfOneExamSelector), extend the SelectorConfig class (see AllMovesOfOneExamSelectorConfig) and configure it in the solver configuration:

```
s.planner.examples.examination.solver.selector.AllMovesOfOneExamSelectorConfig"/
```

>

Note

It's not possible to directly inject a Selector, Acceptor, Forager OF Termination instance and instead required to also extend a Config class because:

- A SolverFactory can build multiple Solver instances, which each require a distinct Selector, Acceptor, Forager and Termination instance.
- A solver configuration needs to be serializable to and from XML. This makes benchmarking with PlannerBenchmark particularly easy because you can configure different solver variants in XML.
- A config class is often easier and clearer to configure. For example: TerminationConfig translates maximumMinutesSpend and maximumSecondsSpend into maximumTimeMillisSpend.

If you build a better implementation that's not domain specific, consider contributing it back as a pull request on github and we'll take it along in future refactors and optimize it.

Chapter 10. Evolutionary algorithms

10.1. Overview

Evolutionary algorithms work on a population of solutions and evolve that population.

10.2. Evolutionary Strategies

This algorithm has not been implemented yet.

10.3. Genetic algorithms

This algorithm has not been implemented yet.

Chapter 11. Benchmarking and tweaking

11.1. Finding the best configuration

Drools Planner supports several optimization algorithms (as solver phases), but you're probably wondering which is the best one? Although some optimization algorithms generally perform better then others, it really depends on your problem domain. Most solver phases have settings which can be tweaked. Those settings can influence the results a lot, although most solver phases work pretty well out-of-the-box.

Luckily, Drools Planner includes a benchmarker, which allows you to play out different solver phases with different settings against each other, so you can pick the best configuration for your planning problem.

11.2. Building a benchmarker

11.2.1. Adding the extra dependency

The benchmarker is current in the drools-planner-core modules, but it requires an extra dependency on the *JFreeChart* [http://www.jfree.org/jfreechart/] library.

If you use maven, add a dependency in your ${\tt pom.xml}$ file:

```
<dependency>
<groupId>jfree</groupId>
<artifactId>jfreechart</artifactId>
<version>1.0.13</version>
</dependency>
```

This is similar for gradle, ivy and buildr.

If you use ANT, you've probably already copied the required jars from the download zip's binaries directory.

11.2.2. Building a PlannerBenchmark

You can build a PlannerBenchmark instance with the XmlPlannerBenchmarkFactory. Configure it with a benchmark configuration xml file:

```
XmlPlannerBenchmarkFactory plannerBenchmarkFactory = new XmlPlannerBenchmarkFactory();
    plannerBenchmarkFactory.configure("/org/drools/planner/examples/nqueens/
benchmark/nqueensBenchmarkConfig.xml");
```

PlannerBenchmark plannerBenchmark = benchmarkFactory.buildPlannerBenchmark();
plannerBenchmark.benchmark();

A basic benchmark configuration file looks something like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<plannerBenchmark>
  <benchmarkDirectory>local/data/nqueens</benchmarkDirectory>
  <warmUpSecondsSpend>30</warmUpSecondsSpend>
  <inheritedSolverBenchmark>
    <problemBenchmarks>
     <xstreamAnnotatedClass>org.drools.planner.examples.nqueens.domain.NQueens
xstreamAnnotatedClass>
              <inputSolutionFile>data/nqueens/unsolved/unsolvedNQueens32.xml
inputSolutionFile>
               <inputSolutionFile>data/nqueens/unsolved/unsolvedNQueens64.xml
inputSolutionFile>
      <problemStatisticType>BEST_SOLUTION_CHANGED</problemStatisticType>
    </problemBenchmarks>
    <solver>
           <solutionClass>org.drools.planner.examples.nqueens.domain.NQueens
solutionClass>
       <planningEntityClass>org.drools.planner.examples.nqueens.domain.Queen
planningEntityClass>
      <scoreDirectorFactory>
        <scoreDefinitionType>SIMPLE</scoreDefinitionType>
                         <scoreDrl>/org/drools/planner/examples/nqueens/solver/
nQueensScoreRules.drl</scoreDrl>
      </scoreDirectorFactory>
      <termination>
        <maximumSecondsSpend>20</maximumSecondsSpend>
      </termination>
      <constructionHeuristic>
                              <constructionHeuristicType>FIRST_FIT_DECREASING
constructionHeuristicType>
<constructionHeuristicPickEarlyType>FIRST_LAST_STEP_SCORE_EQUAL_OR_IMPROVING</
constructionHeuristicPickEarlyType>
      </constructionHeuristic>
    </solver>
  </inheritedSolverBenchmark>
  <solverBenchmark>
    <name>Move tabu</name>
    <solver>
```

```
</solver>
</solverBenchmark>
</plannerBenchmark>
```

This PlannerBenchmark will try 3 configurations (1 move tabu, 1 entity tabu and 1 value tabu) on 2 data sets (32 and 64 queens), so it will run 6 solvers.

Every solverBenchmark entity contains a solver configuration (for example with a local search solver phase) and one or more inputSolutionFile elements. It will run the solver configuration on each of those unsolved solution files. A name is optional and generated if absent.

The common part of multiple <code>solverBenchmark</code> entities can be extracted to the <code>inheritedSolverBenchmark</code> entity, but that can still be overwritten per <code>solverBenchmark</code> entity. Note that inherited solver phases such as <code><constructionHeuristic></code> or <code><localSearch></code> are not overwritten but instead are added to the head of the solver phases list.

You need to specify a benchmarkDirectory (relative to the working directory). The best solution of each solver run and a handy overview HTML file will be written in that directory.

11.2.3. ProblemIO: input and output of Solution files

11.2.3.1. ProblemIO interface

The benchmarker needs to be able to read the input files to contain a *solution* write the best *solution* of each benchmark to an output file. For that it uses a class that implements the *ProblemIO* interface:

```
public interface ProblemIO {
    String getFileExtension();
    Solution read(File inputSolutionFile);
    void write(Solution solution, File outputSolutionFile);
}
```

11.2.3.2. XStreamProblemIO

By default, a XStreamProblemIO instance is used and you just need to configure your Solution class as being annotated with XStream:

<problemBenchmarks>

<xstreamAnnotatedClass>org.drools.planner.examples.nqueens.domain.NQueens</
xstreamAnnotatedClass>

```
<inputSolutionFile>data/nqueens/unsolved/unsolvedNQueens32.xml</
inputSolutionFile>
    ...
    </problemBenchmarks>
```

However, your input files need to have been written with a XStreamProblemIO instance.

11.2.3.3. Custom ProblemIO

Alternatively, you can implement your own ProblemIO implementation and configure it with the problemIOClass element:

<problemBenchmarks>

es.machinereassignment.persistence.MachineReassignmentProblemIO</

11.2.4. Warming up the hotspot compiler

Without a warm up, the results of the first (or first few) benchmarks are not reliable, because they will have lost CPU time on hotspot JIT compilation (and possibly DRL compilation too).

The avoid that distortion, the benchmarker can run some of the benchmarks for a specified amount of time, before running the real benchmarks. Generally, a warm up of 30 seconds suffices:

```
<plannerBenchmark>
...
<warmUpSecondsSpend>30</warmUpSecondsSpend>
...
</plannerBenchmark>
```

11.3. Summary statistics

11.3.1. Best score summary

Several summary statistics of the PlannerBenchmark run will be written in the benchmarkDirectory. Here is an example of a summary statistic:

Figure 11.1. Best score summary statistic

11.4. Statistics per data set (graph and CSV)

The benchmarker supports outputting statistics as graphs and CSV (comma separated values) files to the benchmarkDirectory.

To configure graph and CSV output of a statistic, just add a problemStatisticType line:

```
<plannerBenchmark>
<benchmarkDirectory>local/data/nqueens/solved</benchmarkDirectory>
<inheritedSolverBenchmark>
<problemBenchmarks>
...
<problemStatisticType>BEST_SOLUTION_CHANGED</problemStatisticType>
<problemStatisticType>CALCULATE_COUNT_PER_SECOND</problemStatisticType>
</problemBenchmarks>
....
</inheritedSolverBenchmark>
....
```

</plannerBenchmark>

Multiple problemStatisticType elements are allowed. Some statistic types might influence performance noticeably. The following types are supported:

11.4.1. Best score over time statistic (graph and CSV)

To see how the best score evolves over time, add BEST_SOLUTION_CHANGED as a problemStatisticType.

Figure 11.2. Best score over time statistic

The best score over time statistic is very useful to detect abnormalities, such as score traps.

Note

Don't be fooled by the simulated annealing line in this graph. If you give simulated annealing only 5 minutes, it might still be better than 5 minutes of tabu search.

That's because this simulated annealing implementation automatically determines its velocity based on the amount of time that can be spend. On the other hand, for the tabu search, what you see is what you'd get.

11.4.2. Calculate count per second statistic (graph and CSV)

To see how fast the scores are calculated, add CALCULATE_COUNT_PER_SECOND as a problemStatisticType.

Figure 11.3. Calculate count per second statistic

Note

The initial high calculate count is typical during solution initialization. In this example, it's far easier to calculate the score of a solution if only a handful exams have been added, in contrast to all of them. After those few seconds of initialization, the calculate count is relatively stable, apart from an occasional stop-the-world garbage collector disruption.

11.4.3. Memory use statistic (graph and CSV)

Figure 11.4. Memory use statistic

Chapter 12. Repeated planning

12.1. Introduction to repeated planning

The world constantly changes. The planning facts used to create a solution, might change before or during the execution of that solution. There are 3 types of situations:

- Unforeseen fact changes: For example: an employee assigned to a shift calls in sick, an airplane scheduled to take off has a technical delay, one of the machines or vehicles break down, ... Use **backup planning**.
- Unknown long term future facts: For example: The hospital admissions for the next 2 weeks are reliable, but those for week 3 and 4 are less reliable and for week 5 and beyond are not worth planning yet. Use **continuous planning**.
- Constantly changing planning facts: Use real-time planning.

Waiting to start planning - to lower the risk of planning facts changing - usually isn't a good way to deal with that. More CPU time means a better planning solution. An incomplete plan is better then no plan.

Luckily, the Drools Planner algorithms support planning a solution that's already (partially) planned, known as repeated planning.

12.2. Backup planning

Backup planning is the technique of adding extra score constraints to create space in the planning for when things go wrong. That creates a backup plan in the plan. For example: try to assign an employee as the spare employee (1 for every 10 shifts at the same time), keep 1 hospital bed open in each department, ...

Then, when things go wrong (one of the employees calls in sick), change the planning facts on the original solution (delete the sick employee leave his/her shifts unassigned) and just restart the planning, starting from that solution, which has a different score now. The construction heuristics will fill in the newly created gaps (probably with the spare employee) and the metaheuristics will even improve it further.

12.3. Continuous planning (windowed planning)

Continuous planning is the technique of planning one or more upcoming planning windows at the same time and repeating that process every week (or every day). Because time infinite, there are an infinite future windows, so planning all future windows is impossible. Instead we plan only a number of upcoming planning windows.

Past planning windows are immutable. The first upcoming planning window is considered stable (unlikely to change), while later upcoming planning windows are considered draft (likely to change during the next planning effort). Distant future planning windows are not planned at all.

Past planning windows have *locked* planning entities: the planning entities can no longer be changed (they are locked in place), but some of them are still needed in the score calculation, as they might affect some of the score constraints that apply on the upcoming planning entities. For example: when an employee should not work more than 5 days in a row, he shouldn't work today and tomorrow if he worked the past 4 days already.

Sometimes some planning entities are semi-locked: they can be changed, but occur a certain score penalty if they differ from their original place. For example: avoid rescheduling hospital beds less than 2 days before the patient arrives (unless it's really worth it), avoid changing the airplane gate (or worse, the terminal) during the 2 hours before boarding, ...

Figure 12.1. Continuous planning diagram

Notice the difference between the original planning of November 1th and the new planning of November 5th: some planning facts (F, H, I, J, K) changed, which results in unrelated planning entities (G) changing too.

12.4. Real-time planning (event based planning)

To do real-time planning, first combine backup planning and continuous planning with short planning windows to lower the burden of real-time planning.

While the solver is solving, an outside event might want to change one of the problem facts, for example an airplane is delayed and needs the runway at a later time. Do not change the problem fact instances used by the solver while it is solving, as that will corrupt it. Instead, add a ProblemFactChange to the solver which it will execute in the solver thread as soon as possible.

```
public interface Solver {
    ...
    boolean addProblemFactChange(ProblemFactChange problemFactChange);
    boolean isEveryProblemFactChangeProcessed();
    ...
}
```

```
public interface ProblemFactChange {
    void doChange(ScoreDirector scoreDirector);
}
```

Here's an example:

```
public void deleteComputer(final CloudComputer computer) {
    solver.addProblemFactChange(new ProblemFactChange() {
        public void doChange(ScoreDirector scoreDirector) {
            CloudBalance cloudBalance = (CloudBalance) scoreDirector.getWorkingSolution();
            // First remove the planning fact from all planning entities
    that use it
    for (CloudProcess process : cloudBalance.getProcessList()) {
        if (ObjectUtils.equals(process.getComputer(), computer)) {
            scoreDirector.beforeVariableChanged(process, "computer");
            process.setComputer(null);
            scoreDirector.afterVariableChanged(process, "computer");
            }
            // Next remove it the planning fact itself
        }
    }
}
```

```
for (Iterator<CloudComputer> it = cloudBalance.getComputerList().iterator(); it
CloudComputer workingComputer = it.next();
if (ObjectUtils.equals(workingComputer, computer)) {
    scoreDirector.beforeProblemFactRemoved(workingComputer);
    it.remove(); // remove from list
    scoreDirector.beforeProblemFactRemoved(workingComputer);
    break;
    }
}
}
```

Warning

Any change on the problem facts or planning entities in a ProblemFactChange must be done on the instances of the Solution of scoreDirector.getWorkingSolution(). Note that these are not the same entity instances as in the bestSolution (or therefor your user interface): they are clones.

Warning

Any change on the problem facts or planning entities in a ProblemFactChange must be told to the ScoreDirector.

Note

Many types of changes can leave a planning entity uninitialized, resulting in a partially initialized solution. That's fine, as long as the first solver phase can handle it. All construction heuristics solver phases can handle that, so it's recommended to configure such a SolverPhase as the first phase.

In essence, the Solver will stop, run the ProblemFactChange and restart. Each SolverPhase will run again. Each configured Termination (except terminateEarly) will reset.

Normally, you won't configure any Termination, just call Solver.terminateEarly() when the results are needed. Alternatively, you can subscribe to the BestSolutionChangedEvent. A BestSolutionChangedEvent doesn't guarantee that every ProblemFactChange has been processed already, so check Solver.isEveryProblemFactChangeProcessed() and ignore any BestSolutionChangedEvent fired while that method returns false.
