8.1.2. <a4j:queue> client-side events .................................. 17
9.7.2. Interactivity options ................................................................. 57
9.7.3. Reference data .................................................................... 57
9.8. <rich:select> ........................................................................ 58
  9.8.1. Basic usage .................................................................. 58
  9.8.2. Advanced options .......................................................... 59
  9.8.3. Using manual input .......................................................... 59
  9.8.4. Reference data ................................................................ 59
10. Panels and containers ................................................................. 61
  10.1. <rich:panel> ..................................................................... 61
    10.1.1. Basic usage ................................................................. 61
    10.1.2. Adding a header .......................................................... 61
    10.1.3. Reference data ............................................................ 62
  10.2. <rich:accordion> ................................................................. 62
    10.2.1. Basic usage ................................................................. 63
    10.2.2. Switching panels .......................................................... 63
    10.2.3. <rich:accordion> client-side events ............................... 64
    10.2.4. <rich:accordion> server-side events ............................... 64
    10.2.5. Reference data ............................................................ 64
    10.2.6. <rich:accordionItem> .................................................. 64
  10.3. <rich:collapsiblePanel> ..................................................... 65
    10.3.1. Basic usage ................................................................. 65
    10.3.2. Expanding and collapsing the panel .............................. 65
    10.3.3. Appearance ............................................................... 66
    10.3.4. <rich:collapsiblePanel> server-side events .................... 66
    10.3.5. Reference data ............................................................ 66
  10.4. <rich:popupPanel> ............................................................... 66
    10.4.1. Basic usage ................................................................. 66
    10.4.2. Showing and hiding the pop-up ..................................... 66
    10.4.3. Modal and non-modal panels ....................................... 67
    10.4.4. Size and positioning .................................................... 68
    10.4.5. Contents of the pop-up ................................................. 68
    10.4.6. Header and controls ..................................................... 68
    10.4.7. Reference data ............................................................ 70
  10.5. <rich:tabPanel> ................................................................. 70
    10.5.1. Switching panels .......................................................... 71
    10.5.2. <rich:tabPanel> client-side events ............................... 72
    10.5.3. <rich:tabPanel> server-side events ............................... 72
    10.5.4. Reference data ............................................................ 72
    10.5.5. <rich:tab> ................................................................. 72
  10.6. <rich:togglePanel> ............................................................ 74
    10.6.1. Basic usage ................................................................. 74
    10.6.2. Toggling between components ..................................... 74
    10.6.3. Reference data ............................................................ 75
    10.6.4. <rich:toggleControl> ................................................. 75
14. Output and messages ................................................................. 133
  14.1. <rich:message> ................................................................. 133
      14.1.1. Basic usage ......................................................... 133
      14.1.2. Appearance ...................................................... 133
      14.1.3. Reference data .................................................. 134
  14.2. <rich:messages> ............................................................. 134
      14.2.1. Basic usage ....................................................... 135
      14.2.2. Appearance ..................................................... 135
      14.2.3. Reference data .................................................. 136
  14.3. <rich:progressBar> .......................................................... 136
      14.3.1. Basic usage ....................................................... 137
      14.3.2. Customizing the appearance .................................... 137
      14.3.3. Using set intervals .............................................. 139
      14.3.4. Update mode ..................................................... 139
      14.3.5. Reference data .................................................. 139
  14.4. <rich:toolTip> ............................................................... 139
      14.4.1. Basic usage ....................................................... 140
      14.4.2. Attaching the tool-tip to another component ................ 140
      14.4.3. Appearance ....................................................... 141
      14.4.4. Update mode ..................................................... 141
      14.4.5. <rich:toolTip> client-side events .............................. 142
      14.4.6. Reference data .................................................. 143

15. Drag and drop ................................................................. 145
  15.1. <rich:dragSource> .......................................................... 145
      15.1.1. Basic usage ....................................................... 145
      15.1.2. Dragging an object ............................................... 145
      15.1.3. Reference data .................................................. 145
  15.2. <rich:dropTarget> .......................................................... 146
      15.2.1. Basic usage ....................................................... 146
      15.2.2. Handling dropped data .......................................... 146
      15.2.3. Reference data .................................................. 146
  15.3. <rich:dragIndicator> ..................................................... 147
      15.3.1. Basic usage ....................................................... 147
      15.3.2. Styling the indicator ........................................... 147
      15.3.3. Reference data .................................................. 147

16. Layout and appearance .................................................... 149
  16.1. <rich:jQuery> .............................................................. 149
      16.1.1. Basic usage ....................................................... 149
      16.1.2. Defining a selector ............................................. 149
      16.1.3. Event handlers ................................................ 150
      16.1.4. Timed queries .................................................. 150
      16.1.5. Named queries .................................................. 151
      16.1.6. Dynamic rendering .............................................. 152

  17.5. rich:isUserInRole ................................................................................................. 153
Chapter 1.

Introduction

This book is a guide to the various components available in the RichFaces 4.0 framework. It includes descriptions of the role of the components, details on how best to use them, coded examples of their use, and basic references of their properties and attributes.

For full in-depth references for all component classes and properties, refer to the API Reference available from the RichFaces website.

1.1. Libraries

The RichFaces framework is made up of two tag libraries: the a4j library and the rich library. The a4j tag library represents Ajax4jsf, which provides page-level Ajax support with core Ajax components. This allows developers to make use of custom Ajax behavior with existing components. The rich tag library provides Ajax support at the component level instead, and includes ready-made, self-contained components. These components don't require additional configuration in order to send requests or update.

Ajax support

All components in the a4j library feature built-in Ajax support, so it is unnecessary to add the <a4j:support> behavior.
Common Ajax attributes

The Ajax components in the a4j library share common attributes to perform similar functionality. Most RichFaces components in the rich library that feature built-in Ajax support share these common attributes as well.

Most attributes have default values, so they need not be explicitly set for the component to function in its default state. These attributes can be altered to customize the behavior of the component if necessary.

2.1. Rendering

2.1.1. render

The render attribute provides a reference to one or more areas on the page that need updating after an Ajax interaction. It uses the UIComponent.findComponent() algorithm to find the components in the component tree using their id attributes as a reference. Components can be referenced by their id attribute alone, or by a hierarchy of components’ id attributes to make locating components more efficient. Example 2.1, “render example” shows both ways of referencing components. Each command button will correctly render the referenced panel grids, but the second button locates the references more efficiently with explicit hierarchy paths.

Example 2.1. render example

```html
<h:form id="form1">
    <a4j:commandButton value="Basic reference" render="infoBlock, infoBlock2" />
    <a4j:commandButton value="Specific reference" render=":infoBlock,:sv:infoBlock2" />
</h:form>

<h:panelGrid id="infoBlock">
    ...
</h:panelGrid>

<f:subview id="sv">
    <h:panelGrid id="infoBlock2">
        ...
    </h:panelGrid>
</f:subview>
```

The value of the render attribute can also be an expression written using JavaServer Faces’ Expression Language (EL); this can either be a Set, Collection, Array, or String.
2.1.2. ajaxRendered

A component with ajaxRendered="true" will be re-rendered with every Ajax request, even when not referenced by the requesting component's render attribute. This can be useful for updating a status display or error message without explicitly requesting it.

Rendering of components in this way can be repressed by adding limitRender="true" to the requesting component, as described in Section 2.1.3, "limitRender".

2.1.3. limitRender

A component with limitRender="true" specified will not cause components with ajaxRendered="true" to re-render, and only those components listed in the render attribute will be updated. This essentially overrides the ajaxRendered attribute in other components.

Example 2.3, "Data reference example" describes two command buttons, a panel grid rendered by the buttons, and an output panel showing error messages. When the first button is clicked, the output panel is rendered even though it is not explicitly referenced with the render attribute. The second button, however, uses limitRender="true" to override the output panel's rendering and only render the panel grid.

Example 2.2. Rendering example

```html
<h:form id="form1">
    <a4j:commandButton value="Normal rendering" render="infoBlock" />
    <a4j:commandButton value="Limited rendering" render="infoBlock" limitRender="true" />
</h:form>

<h:panelGrid id="infoBlock">
    ...
</h:panelGrid>

<a4j:outputPanel ajaxRendered="true"/>
```
2.2. Queuing and traffic control

2.2.1. queue

The `queue` attribute defines the name of the queue that will be used to schedule upcoming Ajax requests. Typically RichFaces does not queue Ajax requests, so if events are produced simultaneously they will arrive at the server simultaneously. This can potentially lead to unpredictable results when the responses are returned. The `queue` attribute ensures that the requests are responded to in a set order.

A queue name is specified with the `queue` attribute, and each request added to the named queue is completed one at a time in the order they were sent. In addition, RichFaces intelligently removes similar requests produced by the same event from a queue to improve performance, protecting against unnecessary traffic flooding and

2.2.2. requestDelay

The `requestDelay` attribute specifies an amount of time in milliseconds for the request to wait in the queue before being sent to the server. If a similar request is added to the queue before the delay is over, the original request is removed from the queue and not sent.

2.2.3. ignoreDupResponses

When set to `true`, the `ignoreDupResponses` attribute causes responses from the server for the request to be ignored if there is another similar request in the queue. This avoids unnecessary updates on the client when another update is expected. The request is still processed on the server, but if another similar request has been queued then no updates are made on the client.

2.3. Data processing

RichFaces uses a form-based approach for sending Ajax requests. As such, each time a request is sent the data from the requesting component's parent JSF form is submitted along with the XMLHttpRequest object. The form data contains values from the input element and auxiliary information such as state-saving data.

2.3.1. execute

The `execute` attribute allows JSF processing to be limited to defined components. To only process the requesting component, `execute="@this"` can be used.

2.3.2. immediate

If the `immediate` attribute is set to `true`, the default ActionListener is executed immediately during the Apply Request Values phase of the request processing lifecycle, rather than waitingfor
Chapter 2. Common Ajax attributes

the Invoke Application phase. This allows some data model values to be updated regardless of whether the Validation phase is successful or not.

2.3.3. bypassUpdates

If the bypassUpdates attribute is set to true, the Update Model phase of the request processing lifecycle is bypassed. This is useful if user input needs to be validated but the model does not need to be updated.

2.4. Action and navigation

The action and actionListener attributes can be used to invoke action methods and define action events.

2.4.1. action

The action attribute is a method binding that points to the application action to be invoked. The method can be activated during the Apply Request Values phase or the Invoke Application phase of the request processing lifecycle.

The method specified in the action attribute must return null for an Ajax response with a partial page update.

2.4.2. actionListener

The actionListener attribute is a method binding for ActionEvent methods with a return type of void.

2.5. Events and JavaScript interactions

RichFaces allows for Ajax-enabled JSF applications to be developed without using any additional JavaScript code. However it is still possible to invoke custom JavaScript code through Ajax events.

2.5.1. onsubmit

The onsubmit attribute invokes the JavaScript code before the Ajax request is sent. The request is canceled if the JavaScript code defined for onsubmit returns false.

2.5.2. onbegin

The onbegin attribute invokes the JavaScript code after the Ajax request is sent.

2.5.3. onclick

The onclick attribute functions similarly to the onsubmit attribute for those components that can be clicked, such as <a4j:commandButton> and <a4j:commandLink>. It invokes the defined
JavaScript before the Ajax request, and the request will be canceled if the defined code returns false.

### 2.5.4. onsuccess

The `onsuccess` attribute invokes the JavaScript code after the Ajax response has been returned but *before* the DOM tree of the browser has been updated.

### 2.5.5. oncomplete

The `oncomplete` attribute invokes the JavaScript code after the Ajax response has been returned *and* the DOM tree of the browser has been updated.

---

**Reference consistency**

The code is registered for further invocation of the XMLHttpRequest request object before an Ajax request is sent. As such, using JSF Expression Language (EL) value binding means the code will not be changed during processing of the request on the server. Additionally the `oncomplete` attribute cannot use the `this` keyword as it will not point to the component from which the Ajax request was initiated.

---

### 2.5.6. onerror

The `onerror` attribute invokes the JavaScript code when an error has occurred during Ajax communications.

### 2.5.7. data

The `data` attribute allows the use of additional data during an Ajax call. JSF Expression Language (EL) can be used to reference the property of the managed bean, and its value will be serialized in JavaScript Object Notation (JSON) and returned to the client side. The property can then be referenced through the `data` variable in the event attribute definitions. Both primitive types and complex types such as arrays and collections can be serialized and used with `data`.

**Example 2.3. Data reference example**

```xml
<a4j:commandButton
   value="Update" data="# { userBean.name }
   oncomplete="showTheName(data.name)" />
```
Common features

This chapter covers those attributes and features that are common to many of the components in the tag libraries.

3.1. Positioning and appearance of components

A number of attributes relating to positioning and appearance are common to several components.

- **disabled**
  Specifies whether the component is disabled, which disallows user interaction.

- **focus**
  References the id of an element on which to focus after a request is completed on the client side.

- **height**
  The height of the component in pixels.

- **dir**
  Specifies the direction in which to display text that does not inherit its writing direction. Valid values are LTR (left-to-right) and RTL (right-to-left).

- **style**
  Specifies Cascading Style Sheet (CSS) styles to apply to the component.

- **styleClass**
  Specifies one or more CSS class names to apply to the component.

- **width**
  The width of the component in pixels.

3.2. Calling available JavaScript methods

Client-side JavaScript methods can be called using component events. These JavaScript methods are defined using the relevant event attribute for the component tag. Methods are referenced through typical Java syntax within the event attribute, while any parameters for the methods are obtained through the data attribute, and referenced using JSF Expression Language (EL).

*Example 2.3, “Data reference example”* a simple reference to a JavaScript method with a single parameter.

Refer to *Section 2.5, “Events and JavaScript interactions”* or to event descriptions unique to each component for specific usage.
Part I. Ajax control components
Chapter 4.

Actions

This chapter details the basic components that respond to a user action and submit an Ajax request.

4.1. `<a4j:ajax>`

The `<a4j:ajax>` component allows Ajax capability to be added to any non-Ajax component. It is placed as a direct child to the component that requires Ajax support. The `<a4j:ajax>` component uses the common attributes listed in Chapter 2, Common Ajax attributes.

---

**Attaching JavaScript functions**

When attaching the `<a4j:ajax>` component to non-Ajax JavaServer Faces command components, such as `<h:commandButton>` and `<h:commandLink>`, it is important to set `disabledDefault="true"`. If this attribute is not set, a non-Ajax request is sent after the Ajax request and the page is refreshed unexpectedly.

Example 4.1. `<a4j:ajax>` example

```html
<h:panelGrid columns="2">
    <h:inputText id="myinput" value="#{userBean.name}"
        <a4j:ajax event="keyup" render="outtext" />
    </h:inputText>
    <h:outputText id="outtext" value="#{userBean.name}" />
</h:panelGrid>
```

4.1.1. Reference data

- **component-type**: org.ajax4jsf.Ajax
- **component-class**: org.ajax4jsf.component.html.HtmlAjaxSupport
- **component-family**: org.ajax4jsf.Ajax
- **renderer-type**: org.ajax4jsf.components.AjaxSupportRenderer

4.2. `<a4j:actionParam>`

The `<a4j:actionParam>` behavior combines the functionality of the JavaServer Faces (JSF) components `<f:param>` and `<f:actionListener>`. 
4.2.1. Basic usage

Basic usage of the `<a4j:actionParam>` requires three main attributes:

- `name`, for the name of the parameter;
- `value`, for the initial value of the parameter; and
- `assignTo`, for defining the bean property. The property will be updated if the parent command component performs an action event during the `Process Request` phase.

*Example 4.2. `<a4j:actionParam>` example* shows a simple implementation along with the accompanying managed bean.

**Example 4.2. `<a4j:actionParam>` example**

```xml
<h:form id="form">
    <a4j:commandButton value="Set name to Alex" reRender="rep">
        <a4j:actionparam name="username" value="Alex" assignTo="#{actionparamBean.name}"/>
    </a4j:commandButton>
    <h:outputText id="rep" value="Name: #{actionparamBean.name}"/>
</h:form>
```

```java
public class ActionparamBean {
    private String name = "John";

    public String getName() {
        return name;
    }

    public void setName(String name) {
        this.name = name;
    }
}
```

When the *Set name to Alex* button is pressed, the application sets the `name` parameter of the bean to `Alex`, and displays the name in the output field.

4.2.2. Interoperability

The `<a4j:actionParam>` behavior can be used with non-Ajax components in addition to Ajax components. In this way, data model values can be updated without an JavaScript code on the server side.
The **converter** attribute can be used to specify how to convert the value before it is submitted to the data model. The property is assigned the new value during the **Update Model** phase.

---

**Validation failure**

If the validation of the form fails, the **Update Model** phase will be skipped and the property will not be updated.

Variables from JavaScript functions can be used for the **value** attribute. In such an implementation, the **noEscape** attribute should be set to **true**. Using **noEscape="true"**, the **value** attribute can contain any JavaScript expression or JavaScript function invocation, and the result will be sent to the server as the **value** attribute.

### 4.2.3. Reference data

- **component-type**: `org.ajax4jsf.ActionParameter`
- **component-class**: `org.ajax4jsf.component.html.HTMLActionParameter`

### 4.3. `<a4j:commandButton>`

The `<a4j:commandButton>` is similar to the JavaServer Faces (JSF) component `<h:commandButton>`, but additionally includes Ajax support. When the command button is clicked it submits an Ajax form, and when a response is received the command button can be dynamically rendered.

![Command Button](Command Button)

**Figure 4.1. `<a4j:commandButton>`**

### 4.3.1. Basic usage

The `<a4j:commandButton>` **requires only the value and render attributes to function**. The **value** attribute specifies the text of the button and the **render** attribute specifies which areas are to be updated. The `<a4j:commandButton>` uses the **click** event instead of the **submit** event, but otherwise uses all common Ajax attributes as listed in **Chapter 2, Common Ajax attributes**.

---

**Set disabledDefault="true"**

When attaching a JavaScript function to a `<a4j:commandButton>` with the help of a `<rich:componentControl>`, do not use the **attachTo** attribute of `<rich:componentControl>`. The attribute adds event handlers using **Event.observe** but `<a4j:commandButton>` does not include this event.
4.3.2. Reference data

- component-type: org.ajax4jsf.CommandButton
- component-class: org.ajax4jsf.component.html.HtmlAjaxCommandButton
- component-family: javax.faces.Command
- renderer-type: org.ajax4jsf.components.AjaxCommandButtonRenderer

4.4. <a4j:commandLink>

The <a4j:commandLink> is similar to the JavaServer Faces (JSF) component <h:commandLink>, but additionally includes Ajax support. When the command link is clicked it generates an Ajax form submit, and when a response is received the command link can be dynamically rendered.

Command Link

Figure 4.2. <a4j:commandLink>

4.4.1. Basic usage

The <a4j:commandLink> requires only the value and render attributes to function. The value attribute specifies the text of the link and the render attribute specifies which areas are to be updated. The <a4j:commandLink> uses the click event instead of the submit event, but otherwise uses all common Ajax attributes as listed in Chapter 2, Common Ajax attributes.

4.4.2. Reference data

- component-type: org.ajax4jsf.CommandLink
- component-class: org.ajax4jsf.component.html.HtmlAjaxCommandLink
- component-family: javax.faces.Command
- renderer-type: org.ajax4jsf.components.AjaxCommandLinkRenderer

4.5. <rich:componentControl>

The <rich:componentControl> allows JavaScript API functions to be called on components after defined events. Initialization variants and activation events can be customized, and parameters can be passed to the target component.

4.5.1. Basic usage

The event, for, and operation attributes are all that is required to attach JavaScript functions to the parent component. The event attribute specifies the event that triggers the JavaScript API.
function call. The `for` attribute defines the target component, and the `operation` attribute specifies the JavaScript function to perform.

**Example 4.3. `<rich:componentControl>` basic usage**

```xml
<h:commandButton value="Show Modal Panel">
  <!-- componentControl is attached to the commandButton-->
  <rich:componentControl for="ccModalPanelID" event="click" operation="show"/>
</h:commandButton>
```

The example contains a single command button, which when clicked shows the modal panel with the identifier `ccModalPanelID`.

### 4.5.2. Attaching to a component

The `attachTo` attribute can be used to attach the event to a component other than the parent component. If no `attachTo` attribute is supplied, the `<rich:componentControl>` component's parent is used, as in Example 4.3, `"<rich:componentControl> basic usage"`.

**Example 4.4. Attaching `<rich:componentControl>` to a component**

```xml
<rich:componentControl attachTo="doExpandCalendarID" event="click" operation="Expand" for="ccCalendarID"/>
```

In the example, the click event of the component with the identifier `ccCalendarID` will trigger the Expand operation for the component with the identifier `doExpandCalendarID`.

### 4.5.3. Parameters and JavaScript

The operation can receive parameters either through the `params` attribute, or by using `<f:param>` elements.

**Example 4.5. Using parameters**

The `params` attribute

```xml
<rich:componentControl name="func" event="rowclick" operation="show" params="#{car.model}"/>
```

`<f:param>` elements

```xml
<rich:componentControl event="rowclick" for="menu" operation="show"/>
```
The `name` attribute can be used to define a normal JavaScript function that triggers the specified operation on the target component.

### 4.5.4. Timing

The `attachTiming` attribute can determine the page loading phase during which the `<rich:componentControl>` is attached to the source component:

- **immediate**
  - attached during execution of the script.
- **available**
  - attached after the target component is initialized.
- **load**
  - attached after the page is loaded.

### 4.5.5. Reference data

- `component-type`: `org.richfaces.ComponentControl`
- `component-class`: `org.richfaces.component.html.HtmlComponentControl`
- `component-family`: `org.richfaces.ComponentControl`
- `renderer-type`: `org.richfaces.ComponentControlRenderer`
- `tag-class`: `org.richfaces.taglib.ComponentControlTag`

### 4.6. `<a4j:jsFunction>`

The `<a4j:jsFunction>` component allows Ajax requests to be performed directly from JavaScript code, and server-side data to be invoked and returned in JavaScript Object Notation (JSON) format to use in client-side JavaScript calls.

### 4.6.1. Basic usage

The `<a4j:jsFunction>` component has all the common Ajax action attributes as listed in Chapter 2, Common Ajax attributes; the `action` and `actionListener` attributes can be invoked and parts of the page can be re-rendered after a successful call to the JavaScript function. *Example 4.6, `<a4j:jsFunction> example`* shows how an Ajax request can be initiated from the JavaScript and a partial page update performed. The JavaScript function can be invoked with the data returned by the Ajax response.
Example 4.6. <a4j:jsFunction> example

```html
<h:form>
  ...
  <a4j:jsFunction name="callScript" data="# { bean.someProperty1 }">
    <a4j:actionParam name="param_name" assignTo="# { bean.someProperty2 }" />
  </a4j:jsFunction>
  ...
</h:form>
```

4.6.2. Parameters and JavaScript

The <a4j:jsFunction> component allows the use of the <a4j:actionParam> component or the JavaServer Faces <f:param> component to pass any number of parameters for the JavaScript function.

The <a4j:jsFunction> component is similar to the <a4j:commandButton> component, but it can be activated from the JavaScript code. This allows some server-side functionality to be invoked and the returned data to subsequently be used in a JavaScript function invoked by the complete event attribute. In this way, the <a4j:jsFunction> component can be used instead of the <a4j:commandButton> component.

4.6.3. Reference data

- component-type: org.ajax4jsf.Function
- component-class: org.ajax4jsf.component.html.HtmlajaxFunction
- component-family: org.ajax4jsf.components.ajaxFunction
- renderer-type: org.ajax4jsf.components.ajaxFunctionRenderer

4.7. <a4j:poll>

The <a4j:poll> component allows periodical sending of Ajax requests to the server. It is used for repeatedly updating a page at specific time intervals.

4.7.1. Timing options

The interval attribute specifies the time in milliseconds between requests. The default for this value is 1000 ms (1 second).

The timeout attribute defines the response waiting time in milliseconds. If a response isn't received within the timeout period, the connection is aborted and the next request is sent. By default, the timeout is not set.
The `<a4j:poll>` component can be enabled and disabled using the `enabled` attribute. Using Expression Language (EL), the `enabled` attribute can point to a bean property to apply a particular attribute value.

### 4.7.2. Reference data

- `component-type`: `org.ajax4jsf.Poll`
- `component-class`: `org.ajax4jsf.component.html.AjaxPoll`
- `component-family`: `org.ajax4jsf.components.AjaxPoll`
- `renderer-type`: `org.ajax4jsf.components.AjaxPollRenderer`

### 4.8. `<a4j:push>`

The `<a4j:push>` component periodically performs an Ajax request to the server, simulating "push" functionality. While it is not strictly pushing updates, the request is made to minimal code only, not to the JSF tree, checking for the presence of new messages in the queue. The request registers `EventListener`, which receives messages about events, but does not poll registered beans. If a message exists, a complete request is performed. This is different from the `<a4j:poll>` component, which performs a full request at every interval.

#### 4.8.1. Timing options

The `interval` attribute specifies the time in milliseconds between checking for messages. The default for this value is 1000 ms (1 second). It is possible to set the interval value to 0, in which case it is constantly checking for new messages.

The `timeout` attribute defines the response waiting time in milliseconds. If a response isn't received within the timeout period, the connection is aborted and the next request is sent. By default, the timeout is not set. In combination with the `interval` attribute, checks for the queue state can short polls or long connections.

### 4.8.2. Reference data

- `component-type`: `org.ajax4jsf.Push`
- `component-class`: `org.ajax4jsf.component.html.AjaxPush`
- `component-family`: `org.ajax4jsf.components.AjaxPush`
- `renderer-type`: `org.ajax4jsf.components.AjaxPushRenderer`
Resources

This chapter covers those components used to handle and manage resources and beans.

5.1. `<a4j:keepAlive>`

The `<a4j:keepAlive>` component allows the state of a managed bean to be retained between Ajax requests.

Managed beans can be declared with the `request scope` in the `faces-config.xml` configuration file, using the `<managed-bean-scope>` tag. Any references to the bean instance after the request has ended will cause the server to throw an illegal argument exception (`IllegalArgumentException`). The `<a4j:keepAlive>` component avoids this by maintaining the state of the whole bean object for subsequent requests.

5.1.1. Basic usage

The `beanName` attribute defines the request-scope managed bean name to keep alive.

Example 5.1. `<a4j:keepAlive>` example

```xml
<a4j:keepAlive beanName="testBean" />
```

5.1.2. Non-Ajax requests

The `ajaxOnly` attribute determines whether or not the value of the bean should be available during non-Ajax requests; if `ajaxOnly="true"`, the request-scope bean keeps its value during Ajax requests, but any non-Ajax requests will re-create the bean as a regular request-scope bean.

5.1.3. Reference data

- `component-type:org.ajax4jsf.components.KeepAlive`
- `component-class:org.ajax4jsf.components.AjaxKeepAlive`
- `component-family:org.ajax4jsf.components.AjaxKeepAlive`
Containers

This chapter details those components in the a4j tag library which define an area used as a container or wrapper for other components.

6.1. <a4j:include>

The <a4j:include> component allows one view to be included as part of another page. This is useful for applications where multiple views might appear on the one page, with navigation between the views. Views can use partial page navigation in Ajax mode, or standard JSF navigation for navigation between views.

6.1.1. Basic usage

The viewId attribute is required to reference the resource that will be included as a view on the page. It uses a full context-relative path to point to the resource, similar to the paths used for the <from-view-id> and <to-view-id> tags in the faces-config.xml JSF navigation rules.

Example 6.1. A wizard using <a4j:include>

The page uses <a4j:include> to include the first step of the wizard:

```xml
<h:panelGrid width="100%" columns="2">
    <a4j:keepAlive beanName="profile" />
    <rich:panel>
        <f:facet name="header">
            <h:outputText value="A wizard using a4j:include" />
        </f:facet>
        <h:form>
            <a4j:include viewId="/richfaces/include/examples/wstep1.xhtml" />
        </h:form>
    </rich:panel>
</h:panelGrid>
```

The first step is fully contained in a separate file, wstep1.xhtml. Subsequent steps are set up similarly with additional Previous buttons.

```xml
<ui:composition xmlns="http://www.w3.org/1999/xhtml"
    xmlns:ui="http://java.sun.com/jsf/facesets"
    xmlns:h="http://java.sun.com/jsf/html"
    xmlns:f="http://java.sun.com/jsf/core"
    xmlns:a4j="http://richfaces.org/a4j"
    xmlns:rich="http://richfaces.org/rich">
    <div style="position:relative;height:140px">
```
The navigation is defined in the faces-config.xml configuration file:

```xml
<navigation-rule>
    <from-view-id>/richfaces/include/examples/wstep1.xhtml</from-view-id>
    <navigation-case>
        <from-outcome>next</from-outcome>
        <to-view-id>/richfaces/include/examples/wstep2.xhtml</to-view-id>
    </navigation-case>
</navigation-rule>

<navigation-rule>
    <from-view-id>/richfaces/include/examples/wstep2.xhtml</from-view-id>
    <navigation-case>
        <from-outcome>previous</from-outcome>
        <to-view-id>/richfaces/include/examples/wstep1.xhtml</to-view-id>
    </navigation-case>
</navigation-rule>

<navigation-rule>
    <from-view-id>/richfaces/include/examples/wstep2.xhtml</from-view-id>
    <navigation-case>
        <from-outcome>next</from-outcome>
        <to-view-id>/richfaces/include/examples/finalStep.xhtml</to-view-id>
    </navigation-case>
</navigation-rule>

<navigation-rule>
    <from-view-id>/richfaces/include/examples/finalStep.xhtml</from-view-id>
    <navigation-case>
        <from-outcome>previous</from-outcome>
        <to-view-id>/richfaces/include/examples/wstep2.xhtml</to-view-id>
    </navigation-case>
</navigation-rule>
```
6.1.2. Reference data

- component-type: org.ajax4jsf.Include
- component-class: org.ajax4jsf.component.html.Include
- component-family: javax.faces.Output
- renderer-type: org.ajax4jsf.components.AjaxIncludeRenderer

6.2. `<a4j:outputPanel>`

The `<a4j:outputPanel>` component is used to group together components in to update them as a whole, rather than having to specify the components individually.

6.2.1. Panel appearance

The layout attribute can be used to determine how the component is rendered in HTML:

- layout="inline" is the default behavior, which will render the component as a pair of `<span>` tags containing the child components.
- layout="block" will render the component as a pair of `<div>` tags containing the child components, which will use any defined `<div>` element styles.
- layout="none" will render the component as a pair of `<span>` tags with an identifier equal to that of a child component. If the child component is rendered then the `<span>` are not included, leaving no markup representing the `<a4j:outputPanel>` in HTML.

Setting ajaxRendered="true" will cause the `<a4j:outputPanel>` to be updated with each Ajax response for the page, even when not listed explicitly by the requesting component. This can in turn be overridden by specific attributes on any requesting components.

6.2.2. Reference data

- component-type: org.ajax4jsf.OutputPanel
- component-class: org.ajax4jsf.component.html.HtmlAjaxOutputPanel
- component-family: javax.faces.Panel
- renderer-type: org.ajax4jsf.components.AjaxOutputPanelRenderer

6.3. `<a4j:region>`

The `<a4j:region>` component specifies a part of the document object model (DOM) tree to be processed on the server. The processing includes data handling during decoding, conversion,
validation, and model updating. When not using `<a4j:region>`, the entire view functions as a region.

The whole form is still submitted to the server, but only the specified region is processed. Regions can be nested, in which case only the immediate region of the component initiating the request will be processed.

### 6.3.1. Reference data

- `component-type`: `org.ajax4jsf.AjaxRegion`
- `component-class`: `org.ajax4jsf.component.html.HtmlAjaxRegion`
- `component-family`: `org.ajax4jsf.AjaxRegion`
- `renderer-type`: `org.ajax4jsf.components.AjaxRegionRenderer`
Validation

This chapter covers those components that validate user input. The components enhance JSF validation capabilities with Ajax support and the use of Hibernate validators.

7.1. <rich:ajaxValidator>

The <rich:ajaxValidator> component provides Ajax validation for JSF inputs. It is added as a child component to a JSF tag, and the event attribute specifies when to trigger the validation.

Example 7.1. <rich:ajaxValidator> example

This example shows the use of <rich:ajaxValidator> with standard JSF validators. The validators check the length of the entered name, and the range of the entered age.

```xml
<rich:panel>
    <f:facet name="header">
        <h:outputText value="User Info:"/>
    </f:facet>
    <h:panelGrid columns="3">
        <h:outputText value="Name:"/>
        <h:inputText value="#{userBean.name}" id="name" required="true">
            <f:validateLength minimum="3" maximum="12"/>
            <rich:ajaxValidator event="blur"/>
        </h:inputText>
        <rich:message for="name"/>

        <h:outputText value="Age:"/>
        <h:inputText value="#{userBean.age}" id="age" required="true">
            <f:convertNumber integerOnly="true"/>
            <f:validateLongRange minimum="18" maximum="99"/>
            <rich:ajaxValidator event="blur"/>
        </h:inputText>
        <rich:message for="age"/>
    </h:panelGrid>
</rich:panel>
```

7.1.1. Custom validators

The <rich:ajaxValidator> component can also work with custom validators made using the JSF Validation API in the javax.faces.validator package, or with Hibernate Validator. Refer to the Hibernate Validator documentation for details on how to use Hibernate Validator.
Example 7.2. Using `<rich:ajaxValidator>` with Hibernate Validator

This example shows the use of `<rich:ajaxValidator>` with Hibernate Validator. It validates the entered name, email, and age.

```xml
<h:form id="ajaxValidatorForm2">
  <rich:panel>
    <f:facet name="header">
      <h:outputText value="User Info:" />
    </f:facet>
    <h:panelGrid columns="3">
      <h:outputText value="Name:" />
      <h:inputText value="#{validationBean.name}" id="name" required="true">
        <rich:ajaxValidator event="blur" />
      </h:inputText>
      <rich:message for="name" />
      <h:outputText value="Email:" />
      <h:inputText value="#{validationBean.email}" id="email">
        <rich:ajaxValidator event="blur" />
      </h:inputText>
      <rich:message for="email" />
      <h:outputText value="Age:" />
      <h:inputText value="#{validationBean.age}" id="age">
        <rich:ajaxValidator event="blur" />
      </h:inputText>
      <rich:message for="age" />
    </h:panelGrid>
  </rich:panel>
</h:form>
```

The validation is performed using the `ValidationBean` class:

```java
package org.richfaces.demo.validation;

import org.hibernate.validator.Email;
import org.hibernate.validator.Length;
import org.hibernate.validator.Max;
import org.hibernate.validator.Min;
import org.hibernate.validator.NotEmpty;
import org.hibernate.validator.NotNull;
import org.hibernate.validator.Pattern;

public class ValidationBean {

  private String progressString = "Fill the form in";
```
@NotEmpty
@Pattern(regex=".*[\s].*", message="This string contains only spaces")
@Length(min=3,max=12)
private String name;

@Email
@NotEmpty
private String email;

@NotNull
@Min(18)
@Max(100)
private Integer age;

public ValidationBean() {
}

public String getName() {
    return name;
}

public void setName(String name) {
    this.name = name;
}

public String getEmail() {
    return email;
}

public void setEmail(String email) {
    this.email = email;
}

public Integer getAge() {
    return age;
}

public void setAge(Integer age) {
    this.age = age;
}

public void success() {
    setProgressString(getProgressString() + "(Stored successfully)");
}

public String getProgressString() {
    return progressString;
}

public void setProgressString(String progressString) {
    this.progressString = progressString;
Chapter 7. Validation

7.1.2. Reference data

- `component-type`: org.richfaces.ajaxValidator
- `component-class`: org.richfaces.component.html.HtmlajaxValidator
- `component-family`: org.richfaces.ajaxValidator
- `renderer-type`: org.richfaces.ajaxValidatorRenderer
- `tag-class`: org.richfaces.taglib.ajaxValidatorTag

7.2. `<rich:beanValidator>`

The `<rich:beanValidator>` component provides model-based constraints using Hibernate Validator. This allows Hibernate Validator to be used similar to its use with Seam-based applications.

7.2.1. Basic usage

The `summary` attribute is used for displaying messages about validation errors.

Example 7.3. `<rich:beanValidator>` example

This example shows the bean-based validation of a simple form, containing the user's name, email, and age. The `<rich:beanValidator>` component is defined in the same way as for JSF validators.

```xml
<h:form id="beanValidatorForm">
    <rich:panel>
        <f:facet name="header">
            <h:outputText value="#{validationBean.progressString}" id="progress"/>
        </f:facet>
    </rich:panel>
</h:form>
```
The accompanying bean contains the validation data:

```java
package org.richfaces.demo.validation;

import org.hibernate.validator.Email;
import org.hibernate.validator.Length;
import org.hibernate.validator.Max;
import org.hibernate.validator.Min;
import org.hibernate.validator.NotEmpty;
import org.hibernate.validator.NotNull;
import org.hibernate.validator.Pattern;

public class ValidationBean {

    private String progressString = "Fill the form in";

    @NotEmpty
    @Pattern(regex=".*[\s].*", message="This string contains only spaces")
    @Length(min=3, max=12)
    private String name;

    @Email
```
@NotEmpty
private String email;

@NotNull
@Min(18)
@Max(100)
private Integer age;

public ValidationBean() {
}

public String getName() {
    return name;
}

public void setName(String name) {
    this.name = name;
}

public String getEmail() {
    return email;
}

public void setEmail(String email) {
    this.email = email;
}

public Integer getAge() {
    return age;
}

public void setAge(Integer age) {
    this.age = age;
}

public void success() {
    setProgressString(getProgressString() + "(Stored successfully)" );
}

public String getProgressString() {
    return progressString;
}

public void setProgressString(String progressString) {
    this.progressString = progressString;
}
7.2. Reference data

• component-type: org.richfaces.beanValidator
• component-class: org.richfaces.component.html.HtmlbeanValidator
• component-family: org.richfaces.beanValidator
• renderer-type: org.richfaces.beanValidatorRenderer
• tag-class: org.richfaces.taglib.beanValidatorTag

7.3. <rich:graphValidator>

The <rich:graphValidator> component is used to wrap a group of input components for overall validation with Hibernate Validators. This is different from the <rich:beanValidator> component, which is used as a child element to individual input components.

7.3.1. Basic usage

The summary attribute is used for displaying messages about validation errors.

Example 7.4. <rich:graphValidator> example

This example shows the validation of a simple form, containing the user’s name, email, and age. The <rich:graphValidator> component wraps the input components to validate them together.
Chapter 7. Validation

The accompanying bean contains the validation data:

```java
package org.richfaces.demo.validation;

import org.hibernate.validator.Email;
import org.hibernate.validator.Length;
import org.hibernate.validator.Max;
import org.hibernate.validator.Min;
import org.hibernate.validator.NotEmpty;
import org.hibernate.validator.NotNull;
import org.hibernate.validator.Pattern;

public class ValidationBean {

    private String progressString = "Fill the form in";

    @NotEmpty
    @Pattern(regex=".*[\^\s].*", message="This string contains only spaces")
    @Length(min=3, max=12)
    private String name;

    @Email
    @NotEmpty
    private String email;

    @NotNull

```
@Min(18)  
@Max(100)  
private Integer age;

public ValidationBean() {
}

public String getName() {
    return name;
}

public void setName(String name) {
    this.name = name;
}

public String getEmail() {
    return email;
}

public void setEmail(String email) {
    this.email = email;
}

public Integer getAge() {
    return age;
}

public void setAge(Integer age) {
    this.age = age;
}

public void success() {
    setProgressString(getProgressString() + "(Stored successfully)");
}

public String getProgressString() {
    return progressString;
}

public void setProgressString(String progressString) {
    this.progressString = progressString;
}
7.3.2. Bean values

The optional `value` attribute can be used to define a value bound to the bean. The bean properties are then validated again after the model has been updated.

**Example 7.5. Using the `value` attribute**

```html
<h:form id="graphValidatorForm2">
    <a4j:region renderRegionOnly="true">
        <rich:graphValidator summary="Invalid values: 
            value="#{dayStatistics}"">
            <table>
                <thead>
                    <tr>
                        <th>Activity</th>
                        <th>Time</th>
                    </tr>
                </thead>
                <tbody>
                    <a4j:repeat value="#{dayStatistics.dayPasstimes}" var="pt" id="table">
                        <tr>
                            <td align="center" width="100px"><h:outputText value="#{pt.title}" /></td>
                            <td align="center" width="100px"><rich:inputNumberSpinner minValue="0" maxValue="24" value="#{pt.time}" id="time">
                                <rich:message for="time" /></td>
                            <td><rich:message for="time" /></td>
                        </tr>
                    </a4j:repeat>
                </tbody>
            </table>
        </rich:graphValidator>
    </a4j:region>
    <a4j:commandButton value="Store my details"
        actionListener="#{dayStatistics.store}" reRender="panel" />
</h:form>
```
7.3.3. Reference data

- `component-type` : `org.richfaces.graphValidator`
- `component-class` : `org.richfaces.component.html.HtmlgraphValidator`
- `component-family` : `org.richfaces.graphValidator`
- `renderer-type` : `org.richfaces.graphValidatorRenderer`
- `tag-class` : `org.richfaces.taglib.graphValidatorTag`
Processing management

This chapter covers those components that manage the processing of information, requests, and updates.

8.1. `<a4j:queue>`

The `<a4j:queue>` component manages a queue of Ajax requests to control message processing.

8.1.1. Queue size

The `size` attribute specifies the number of requests that can be stored in the queue at a time; smaller queue sizes help prevent server overloads. When the queue's size is exceeded, the `sizeExceededBehavior` determines the way in which the queue handles the requests:

- `dropNext` drops the next request currently in the queue.
- `dropNew` drops the incoming request.
- `fireNext` immediately sends the next request currently in the queue.
- `fireNew` immediately sends the incoming request.

8.1.2. `<a4j:queue>` client-side events

The `<a4j:queue>` component features several events relating to queuing actions:

- The `complete` event attribute is fired after a request is completed. The request object is passed as a parameter to the event handler, so the queue is accessible using `request.queue` and the element which was the source of the request is accessible using `this`.
- The `requestqueue` event attribute is fired after a new request has been added to the queue.
- The `requestdequeue` event attribute is fired after a request has been removed from the queue.
- The `sizeexceeded` event attribute is fired when the queue has been exceeded.
- The `submit` event attribute is fired before the request is sent.
- The `success` event attribute is fired after a successful request but before the DOM is updated on the client side.

8.1.3. Reference data

- `renderer-type': org.ajax4jsf.QueueRenderer
- `component-class': org.ajax4jsf.component.html.HtmlQueue
8.2. \(<\text{a4j:log}>\)

The \(<\text{a4j:log}>\) component generates JavaScript that opens a debug window, logging application information such as requests, responses, and DOM changes.

### 8.2.1. Log monitoring

The popup attribute causes the logging data to appear in a new pop-up window if set to true, or in place on the current page if set to false. The window is set to be opened by pressing the key combination Ctrl-Shift-L; this can be partially reconfigured with the hotkey attribute, which specifies the letter key to use in combination with Ctrl-Shift instead of L.

The amount of data logged can be determined with the level attribute:

- ERROR
- FATAL
- INFO
- WARN
- ALL, the default setting, logs all data.

**Example 8.1. \(<\text{a4j:log}>\) example**

```
<\text{a4j:log} level="ALL" popup="false" width="400" height="200" />
```

#### Log renewal

The log is automatically renewed after each Ajax request. It does not need to be explicitly re-rendered.

### 8.2.2. Reference data

- component-type: org.ajax4jsf.Log
- component-class: org.ajax4jsf.component.html.AjaxLog
- component-family: org.ajax4jsf.Log
8.3. `<a4j:status>`

The `<a4j:status>` component displays the status of current Ajax requests; the status can be either in progress or complete.

8.3.1. Customizing the text

The `startText` attribute defines the text shown after the request has been started and is currently in progress. This text can be styled with the `startStyle` and `startStyleClass` attributes. Similarly, the `stopText` attribute defines the text shown once the request is complete, and text is styled with the `stopStyle` and `stopStyleClass` attributes. Alternatively, the text styles can be customized using facets, with the facet name set to either `start` or `stop` as required. If the `stopText` attribute is not defined, and no facet exists for the stopped state, the status is simply not shown; in this way only the progress of the request is displayed to the user.

**Example 8.2. Basic `<a4j:status>` usage**

```xml
<a4j:status startText="In progress..." stopText="Complete" />
```

8.3.2. Specifying a region

The `<a4j:status>` component works for each Ajax component inside the local region. If no region is defined, every request made on the page will activate the `<a4j:status>` component. Alternatively, the `<a4j:status>` component can be linked to specific components in one of two ways:

- The `for` attribute can be used to specify the component for which the status is to be monitored.
- With an `id` identifier attribute specified for the `<a4j:status>`, individual components can have their statuses monitored by referencing the identifier with their own `status` attributes.

**Example 8.3. Updating a common `<a4j:status>` component**

```xml
<a4j:region id="extr">
    <h:outputText value="Status:" />
    <a4j:status id="commonstatus" startText="In Progress...." stopText="" />
</a4j:region>

<a4j:region id="intr">
    <h:panelGrid columns="2">
        <h:outputText value="Name" />
        <h:inputText id="name" value="#{userBean.name}" />
    </h:panelGrid>
</a4j:region>
```
8.3.3. Reference data

- component-type: org.ajax4jsf.Status
- component-class: org.ajax4jsf.component.html.HtmlAjaxStatus
- component-family: javax.faces.Panel
- renderer-type: org.ajax4jsf.components.AjaxStatusRenderer
Part II. User interface components
Rich inputs

Documentation in development

Some concepts covered in this chapter may refer to the previous version of Richfaces, version 3.3.3. This chapter is scheduled for review to ensure all information is up to date.

This chapter details rich components for user input and interaction.

9.1. <rich:autocomplete>

The `<rich:autocomplete>` component is an auto-completing input-box with built-in Ajax capabilities. It supports client-side suggestions, browser-like selection, and customization of the look and feel.

![Autocomplete example](image)

**Figure 9.1. `<rich:autocomplete>`**

9.1.1. Basic usage

The `value` attribute stores the text entered by the user for the auto-complete box. Suggestions shown in the auto-complete list can be specified using the `autocompleteMethod` attribute, which points to a collection of suggestions.

**Example 9.1. Defining suggestion values**

```xml
<rich:autocomplete value="#{bean.state}" autocompleteMethod="#{bean.suggestions}"/>
```

9.1.2. Interactivity options

Users can type into the text field to enter a value, which also searches through the suggestion items in the drop-down box. By default, the first suggestion item is selected as the user types. This behavior can be deactivated by setting `selectFirst="false"`. 
Chapter 9. Rich inputs

Setting `autoFill="true"` causes the combo-box to fill the text field box with a matching suggestion as the user types.

9.1.3. Customizing the filter

The `<rich:autocomplete>` component uses the JavaScript `startsWith()` method to create the list of suggestions. The filtering is performed on the client side. Alternatively, use the `clientFilter` attribute to specify a custom filtering function. The custom function must accept two parameters: the `subString` parameter is the filtering value as typed into the text box by the user, and the `value` parameter is an item in the list of suggestions against which the `subString` must be checked. Each item is iterated through and passed to the function as the `value` parameter. The custom function must return a boolean value indicating whether the passed item meets the conditions of the filter, and the suggestion list is constructed from successful items.

Example 9.2. Customizing the filter

This example demonstrates how to use a custom filter with the `clientFilter` attribute. The custom filter determines if the sub-string is contained anywhere in the suggestion item, instead of just at the start.

```xml
<script>
function customFilter(subString, value){
    if(subString.length>=1) {
        if(value.indexOf(subString)!=-1)
            return true;
    }else return false;
}
</script>

<h:form>
    <rich:autocomplete mode="client" minChars="0" autofill="false"
                      clientFilter="customFilter"
                      autocompleteMethod="# {autocompleteBean.autocomplete}"
                      autocompleteMethod="#{autocompleteBean.autocomplete}" />
</h:form>

9.1.4. Reference data

- `component-type:org.richfaces.autocomplete`
- `component-class:org.richfaces.component.html.HtmlAutocomplete`
- `component-family:org.richfaces.autocomplete`
- `renderer-type:org.richfaces.renderkit.autocompleteRenderer`
- `tag-class:org.richfaces.taglib.autocompleteTag`
9.2. \texttt{<rich:calendar>}

The \texttt{<rich:calendar>} component allows the user to enter a date and time through an in-line or pop-up calendar. The pop-up calendar can navigate through months and years, and its look and feel can be highly customized.

![Calendar Component Example](image)

*Figure 9.2. \texttt{<rich:calendar>}*

9.2.1. Basic usage

Basic usage of the \texttt{<rich:calendar>} component requires only the \texttt{value} attribute, which holds the currently selected date. Example 9.3, "Basic usage" shows a basic declaration, with the value pointing to a data model.

**Example 9.3. Basic usage**

\begin{verbatim}
<rich:calendar value="#{bean.dateTest}" />
\end{verbatim}

9.2.2. Using a data model

The \texttt{<rich:calendar>} component supports two different ways of loading data through defining the \texttt{mode} attribute. When not specified, the component uses \texttt{client} mode, which loads an initial portion of data within a set date range. The range can be defined by using the \texttt{preloadDateRangeBegin} and \texttt{preloadDateRangeEnd} attributes. Additional data requests are not sent.

Alternatively, with \texttt{mode="ajax"} the \texttt{<rich:calendar>} requests portions of data for rendering from a special data model. The data model can be defined through the \texttt{dataModel} attribute, which points to an object that implements the \texttt{CalendarDataModel} interface. If the \texttt{dataModel} attribute is not defined or has a value of \texttt{null}, the \texttt{ajax} mode functions the same as the \texttt{client} mode.
9.2.3. Client-side customization

Instead of using a data model, the `<rich:calendar>` component can be customized on the client-side. Example 9.4, “Client-side customization” demonstrates how client-side customization can be used to style different days in a calendar.

Example 9.4. Client-side customization

```html
<style>
  .everyThirdDay {
    background-color: gray;
  }
  .weekendBold {
    font-weight: bold;
    font-style: italic;
  }
</style>
<script type="text/javascript">
  var curDt = new Date();
  function disablementFunction(day){
    if (day.isWeekend) return false;
    if (curDt===undefined){
      curDt = day.date.getDate();
    }
    if (curDt.getTime() - day.date.getTime() &lt; 0) return true;
    else return false;
  }
  function disabledClassesProv(day){
    if (curDt.getTime() - day.date.getTime() &gt;= 0) return 'rf-ca-boundary-dates';
    var res = '';
    if (day.isWeekend) res+='weekendBold ';
    if (day.day%3==0) res+='everyThirdDay';
    return res;
  }
</script>
<rich:calendar dayDisableFunction="disablementFunction"
    dayClassFunction="disabledClassesProv"
    boundaryDatesMode="scroll"/>
```

9.2.4. Behavior and appearance

The `<rich:calendar>` component is presented as a pop-up by default, appearing as a text field with a button to expand the full pop-up calendar. To render the calendar in-line on the page instead, set `popup="false`. This displays the full calendar without the text field or display button.
To add keyboard support for manual input, set `enableManualInput="true"`. To disable the calendar from any user input, set `disabled="true"`.

To change the appearance of the display button from the standard calendar icon, use the `buttonIcon` and `buttonDisabledIcon` attributes to replace the icon with a specified file. Alternatively, use the `buttonLabel` attribute to display text on the button without an icon. If `buttonLabel` is specified then both the `buttonIcon` and `buttonDisabledIcon` attributes are ignored. To hide the text field box, set `showInput="false"`.

The calendar features a **Today** button for locating today's date on the calendar. This can be set to three different values using the `todayControlMode` attribute:

- **hidden**, which does not display the button;
- **select**, the default setting, which scrolls the calendar to the current month and selects today's date; and
- **scroll**, which scrolls the calendar to the current month but does not select today's date.

To make the entire calendar read-only, set `readonly="true"`. This allows months and years to be browsed through with the arrow controls, but dates and times cannot be selected.

The styling and appearance of the calendar can be fully customized using facets. The `header` and `footer` facets define the calendar's header and footer. The `optionalHeader` and `optionalFooter` facets define the calendar's optional header and optional footer. The `weekNumber` facet controls the appearance of the week numbers, and the `weekDay` facet controls the appearance of the individual day cells on the calendar. Figure 9.3, “Facet elements” shows some of the elements available for customization through the various facets.

![Figure 9.3. Facet elements](image-url)
9.2.5. Time of day

The `<rich:calendar>` component can additionally allow a time of day to be specified with the date. After selecting a date the option to set a time becomes available. The default time can be set with the `defaultTime` attribute. If the time is altered and a new date is selected, it will not reset unless `resetTimeOnDateSelect="true"` is specified.

Support for seconds

In RichFaces 4, the `<rich:calendar>` component supports times that include seconds. Previous versions of RichFaces only supported hours and minutes.

9.2.6. Localization and formatting

Date and time strings can be formatted in a set pattern. Use standard locale formatting strings specified by ISO 8601 (for example, `d/M/yy  HH:mm a`) with the `datePattern` attribute to format date and time strings.

To set the locale of the calendar, use the `locale` attribute. The calendar will render month and day names in the relevant language. For example, to set the calendar to the US locale, specify `locale="en/US"`.

9.2.7. JavaScript API

The `<rich:calendar>` component can be controlled through the JavaScript API. The JavaScript API provides the following functions:

- `selectDate(date)`
  Select the specified date. If the date is not in the currently displayed month, a request is performed to display the correct month.

- `isDateEnabled(date)`
  Check if the specified date is able to be selected.

- `enableDate(date)`
  Enable the specified date cell control on the calendar.

- `disableDate(date)`
  Disable the specified date cell control on the calendar.

- `enableDates(date[])`
  Enable the specified dates' cell controls on the calendar.

- `disableDates(date[])`
  Disable the specified dates' cell controls on the calendar.
nextMonth()
   Display the next month.

nextYear()
   Display the next year.

prevMonth()
   Display the previous month.

prevYear()
   Display the previous year.

gGetCurrentMonth()
   Return the number of the month currently being displayed.

gGetCurrentYear()
   Return the number of the year currently being displayed.

today()
   Select today's date.

ggetSelectedDate()
   Return the currently selected date.

Object ggetData()
   Return additional data for the date.

resetSelectedDate()
   Clear the selected day value.

doCollapse()
   Collapse the pop-up calendar element.

doExpand()
   Expand the pop-up calendar element.

doSwitch()
   Invert the state of the pop-up calendar element.

9.2.8. Reference data

- component-type: org.richfaces.calendar
- component-class: org.richfaces.component.html.HtmlCalendar
- component-family: org.richfaces.calendar
- renderer-type: org.richfaces.renderkit.calendarRenderer
- tag-class: org.richfaces.taglib.calendarTag
9.3. `<rich:fileUpload>`

The `<rich:fileUpload>` component allows the user to upload files to a server. It features multiple uploads, progress bars, restrictions on file types, and restrictions on sizes to be uploaded.

9.3.1. Basic usage

Basic usage requires the `fileUploadListener` attribute. Use the attribute to call a function on the server side after each file is uploaded.

**Example 9.5. Basic usage**

```xml
<rich:fileUpload fileUploadListener="#{bean.listener}" />
```

9.3.2. Upload settings

Files are uploaded to either the temporary folder (different for each operating system) or to RAM (random-access memory), depending on the value of the `org.richfaces.fileUpload.createTempFile` parameter of the `web.xml` settings file for the project. If the parameter is set to `true`, the files are uploaded to the temporary folder.

To limit the maximum size of the uploaded files, define the byte size with the `org.richfaces.fileUpload.maxRequestSize` parameter of the `web.xml` settings file for the project.

9.3.3. Interactivity options

The text labels used in the component can be completely customized. Labels for the various controls of the component can be set using the following parameters:

- **addLabel**
  - The `addLabel` parameter sets the label for the Add button.

- **clearAllLabel**
  - The `clearAllLabel` parameter sets the label for the Clear All button.

- **clearLabel**
  - The `clearLabel` parameter sets the label for the Clear button.

- **uploadLabel**
  - The `uploadLabel` parameter sets the label for the Upload button.

The progress of a file upload operation can be represented using either a referencing `<rich:progressBar>` component, or the progress facet. Refer to Section 14.3, "<rich:progressBar>" for details on the `<rich:progressBar>` component.
To disable the `<rich:fileUpload>` component, use the disabled attribute.

### 9.3.4. `<rich:fileUpload>` client-side events

There are a number of event handlers specific to the `<rich:fileUpload>` component:

- `filesubmit` is triggered before a file is uploaded.
- `uploadcomplete` is triggered after all files in the list have finished uploading.

### 9.3.5. Reference data

- `component-type`: `org.richfaces.FileUpload`
- `component-class`: `org.richfaces.component.UIFileUpload`
- `component-family`: `org.richfaces.FileUpload`
- `renderer-type`: `org.richfaces.FileUploadRenderer`

### 9.4. `<rich:inplaceInput>`

The `<rich:inplaceInput>` component allows information to be entered in-line in blocks of text, improving readability of the text. Multiple input regions can be navigated with keyboard navigation. The component has three functional states: the “view” state, where the component displays its initial setting, such as "click to edit"; the “edit” state, where the user can input text; and the “changed” state, where the new value for the component has been confirmed but can be edited again if required.

#### 9.4.1. Basic usage

Basic usage requires the `value` attribute to point to the expression for the current value of the component.

#### 9.4.2. Interactivity options

When in the initial "view" state, the starting label can be set using the `defaultLabel` attribute. Once the user has entered text, the label is stored in the model specified by the `value` attribute. The use of the default label and value is shown in Example 9.6, “Default label and value”.

**Example 9.6. Default label and value**

```html
<rich:inplaceInput value="#{bean.value}" defaultLabel="click to edit"/>
```

By default, the event to switch the component to the "edit" state is a single mouse click. This can be changed using the `editEvent` attribute to specify a different event.
The user can confirm and save their input by pressing the **Enter** key or cancel by pressing the **Esc** key. Alternatively, buttons for confirming or canceling can be added to the component by setting `showControls="true"`.

### 9.4.3. Reference data

- **component-type**: org.richfaces.inplaceInput
- **component-class**: org.richfaces.component.html.HtmlInplaceInput
- **component-family**: org.richfaces.inplaceInput
- **renderer-type**: org.richfaces.renderkit.inplaceInputRenderer
- **tag-class**: org.richfaces.taglib.inplaceInputTag

### 9.5. `<rich:inplaceSelect>`

The `<rich:inplaceSelect>` component is similar to the `<rich:inplaceInput>` component, except that the `<rich:inplaceSelect>` component uses a drop-down selection box to enter text instead of a regular text field. Changes can be rendered either in-line or for the whole block, and inputs can be focused with keyboard navigation. The component has three functional states: the "view" state, where the component displays its initial setting, such as "click to edit"; the "edit" state, where the user can select a value from a drop-down list; and the "changed" state, where the new value for the component has been confirmed but can be edited again if required.

![Figure 9.4. `<rich:inplaceSelect>`](image)

### 9.5.1. Basic usage

Basic usage requires the **value** attribute to point to the expression for the current value of the component and a list of items. The list of items can be defined using the JSF components `<f:selectItem/>` and `<f:selectItems/>`. 

---

The opening of a new *click to edit* Ford Company involved rehiring personnel.

The opening of a new *click to edit* d* Company involved rehiring personnel.

The opening of a new *click to edit* *oil well* Factory *newspaper* Ford Company involved rehiring personnel.
Example 9.7. Defining list items for `<rich:inplaceSelect>`

```xml
<rich:inplaceSelect value="#{bean.inputValue}" defaultLabel="click to edit">
    <f:selectItems value="#{bean.selectItems} />
    <f:selectItem itemValue="1" itemLabel="Item 1" />
    <f:selectItem itemValue="2" itemLabel="Item 2" />
    <f:selectItem itemValue="3" itemLabel="Item 3" />
    <f:selectItem itemValue="4" itemLabel="Item 4" />
</rich:comboBox>
```

9.5.2. Interactivity options

When in the initial "view" state, the starting label can be set using the `defaultLabel` attribute, such as `defaultLabel="click to edit"`.

By default, the event to switch the component to the "edit" state is a single mouse click. This can be changed using the `editEvent` attribute to specify a different event. When switching to "edit" mode, the drop-down list of possible values will automatically be displayed; this can be deactivated by setting `openOnEdit="false"`.

Once a new value for the control is saved, the state switches to the "changed" state. Saving a new value for the control can be performed in three different ways:

- Once the user selects an item from the drop-down list, the item is saved as the new control value. This is the default setting.
- If `saveOnBlur="true"` is set, the selected item is saved as the new control value when the control loses focus.
- If `showControls="true"` is set, buttons are added to the control to confirm or cancel the selection. The new control value is only saved once the user confirms the selection using the button.

9.5.3. Reference data

- `component-type`: org.richfaces.inplaceSelect
- `component-class`: org.richfaces.component.html.HtmlInplaceSelect
- `component-family`: org.richfaces.inplaceSelect
- `renderer-type`: org.richfaces.renderkit.inplaceSelectRenderer
- `tag-class`: org.richfaces.taglib.inplaceSelectTag
9.6. `<rich:inputNumberSlider>`

The `<rich:inputNumberSlider>` component provides a slider for changing numerical values. Optional features include control arrows to step through the values, a tool-tip to display the value while sliding, and a text field for typing the numerical value which can then be validated against the slider’s range.

![Slider Example](image)

**Figure 9.5. `<rich:inputNumberSlider>`**

9.6.1. Basic usage

Basic use of the component with no attributes specified will render a slider with a minimum value of 0, a maximum of 100, and a gradient step of 1, together with a text field for typing the desired numerical value. The slider is labeled with the minimum and maximum boundary values, and a tool-tip showing the current value is shown while sliding the slider. The `value` attribute is used for storing the currently selected value of the slider.

9.6.2. Interactivity options

The text field can be removed by setting `showInput="false"`. The properties of the slider can be set with the attributes `minValue`, `maxValue`, and `step`. The minimum and maximum labels on the slider can be hidden by setting `showBoundaryValues="false"`. The tool-tip showing the current value can be hidden by setting `showToolTip="false"`. Arrow controls can be added to either side of the slider to adjust the value incrementally by setting `showArrows="true"`. Clicking the arrows move the slider indicator in that direction by the gradient step, and clicking and holding the arrows moves the indicator continuously. The time delay for each step when updating continuously can be defined using the `delay` attribute.

9.6.3. Reference data

- `component-type: org.richfaces.inputNumberSlider`
9.7. <rich:inputNumberSpinner>

The <rich:inputNumberSpinner> component is a single-line input field with buttons to increase and decrease a numerical value. The value can be changed using the corresponding directional keys on a keyboard, or by typing into the field.

Figure 9.6. <rich:inputNumberSpinner>

9.7.1. Basic usage

Basic use of the component with no attributes specified will render a number spinner with a minimum value of 1, a maximum value of 100, and a gradient step of 1.

These default properties can be re-defined with the attributes minValue, maxValue, and step respectively. The starting value of the spinner is the minimum value unless otherwise specified with the value attribute.

9.7.2. Interactivity options

When changing the value using the buttons, raising the value above the maximum or cause the spinner to restart at the minimum value. Likewise, when lowering below the minimum value the spinner will reset to the maximum value. This behavior can be deactivated by setting cycled="false", which will cause the buttons to stop responding when the reach the maximum or minimum value.

The ability to change the value by typing into the text field can be disabled by setting enableManualInput="false".

9.7.3. Reference data

- component-type: org.richfaces.inputNumberSpinner
- component-class: org.richfaces.component.html.HtmlInputNumberSpinner
- component-family: org.richfaces.inputNumberSpinner
- renderer-type: org.richfaces.renderkit.inputNumberSliderRenderer
- tag-class: org.richfaces.taglib.inputNumberSliderTag
9.8. `<rich:select>`

The `<rich:select>` component provides a drop-down list box for selecting a single value from multiple options. The component supports keyboard navigation and can optionally accept typed input. The `<rich:select>` component functions similarly to the JavaServer Faces `<h:selectOneMenu>` component.

![Figure 9.7. `<rich:select>`](image)

### 9.8.1. Basic usage

Simple usage of the `<rich:select>` component does not need any attributes declared, but child tags to manage the list of selections are required. The child tags can either be a number of `<f:selectItem>` tags or a `<f:selectItems>` tag which points to a data model containing a list of selection items. The `value` attribute is used to store the current selection.

#### Example 9.8. Selection items

**Using multiple `<f:selectItem>` tags**

```xml
<rich:select>
  <f:selectItem itemValue="0" itemLabel="Option 1" />
  <f:selectItem itemValue="1" itemLabel="Option 2" />
  <f:selectItem itemValue="2" itemLabel="Option 3" />
  <f:selectItem itemValue="3" itemLabel="Option 4" />
  <f:selectItem itemValue="4" itemLabel="Option 5" />
</rich:select>
```

**Using a single `<f:selectItems>` tag**

```xml
<rich:select>
  <f:selectItems value="#{bean.options}" />
</rich:select>
```

The arrow keys on a keyboard can be used to highlight different items in the list. If the control loses focus or the **Enter** key is pressed, the highlighted option is chosen as the value and the list is closed. Pressing the **Esc** key will close the list but not change the value.
9.8.2. Advanced options

Use the `defaultLabel` attribute to set a place-holder label, such as `defaultLabel="select an option"`.

Server-side processing occurs in the same manner as for an `<h:selectOneMenu>` component. As such, custom objects used for selection items should use the same converters as for an `<h:selectOneMenu>` component.

9.8.3. Using manual input

Selection lists can allow the user to type into a text field to scroll through or filter the list. By default, the `<rich:select>` component functions as a drop-down list with no manual input. To add keyboard support for manual input, set `enableManualInput="true"`.

Once the user begins typing, the first available matching option is highlighted. If the typed text does not match any values in the list, no value is chosen and the drop-down list displays as empty. Other keyboard interaction remains the same as the basic drop-down list.

9.8.4. Reference data

- `component-type`: `org.richfaces.select`
- `component-class`: `org.richfaces.component.html.HtmlSelect`
- `component-family`: `org.richfaces.select`
- `renderer-type`: `org.richfaces.renderkit.selectRenderer`
- `tag-class`: `org.richfaces.taglib.selectTag`
Panels and containers

Documentation in development

Some concepts covered in this chapter may refer to the previous version of Richfaces, version 3.3.3. This chapter is scheduled for review to ensure all information is up to date.

This chapter details those components which act as panels and containers to hold groups of other components.

10.1. <rich:panel>

The <rich:panel> component is a bordered panel with an optional header.

10.1.1. Basic usage

No attributes need to be listed for basic usage. A <rich:panel> without any attributes defined renders a bordered region with no header.

10.1.2. Adding a header

To add a header to the panel, use the header attribute to specify the text to appear in the header. Alternatively the header can be constructed using a header facet. Example 10.1, “Adding a header” demonstrates the two different approaches.

Example 10.1. Adding a header

```xml
<rich:panel header="This is the panel header">
  <h:outputText value="This is the panel content" />
</rich:panel>
```
<rich:panel>
  <f:facet name="header">
    <h:outputText value="This is the panel header"/>
  </f:facet>
  <h:outputText value="This is the panel content"/>
</rich:panel>

Both the examples render an identical panel.

![Figure 10.2. Adding a header](image)

**10.1.3. Reference data**

- `component-type: org.richfaces.panel`
- `component-class: org.richfaces.component.html.HtmlPanel`
- `component-family: org.richfaces.panel`
- `renderer-type: org.richfaces.panelRenderer`
- `tag-class: org.richfaces.taglib.panelTag`

**10.2. `<rich:accordion>`**

The `<rich:accordion>` is a series of panels stacked on top of each other, each collapsed such that only the header of the panel is showing. When the header of a panel is clicked, it is expanded to show the content of the panel. Clicking on a different header will collapse the previous panel and expand the selected one. Each panel contained in a `<rich:accordion>` component is a `<rich:accordionItem>` component.
10.2.1. Basic usage

The `<rich:accordion>` component requires no attributes for basic usage. The component can contain any number of `<rich:accordionItem>` components as children. The headers of the `<rich:accordionItem>` components control the expanding and collapsing when clicked. Only a single `<rich:accordionItem>` can be displayed at a time. Refer to Section 10.2.6, “<rich:accordionItem>” for details on the `<rich:accordionItem>` component.

10.2.2. Switching panels

The switching mode for performing submissions is determined by the `switchType` attribute, which can have one of the following three values:

**server**

The default setting. Activation of a `<rich:accordionItem>` component causes the parent `<rich:accordion>` component to perform a common submission, completely re-rendering the page. Only one panel at a time is uploaded to the client side.

**ajax**

Activation of a `<rich:accordionItem>` component causes the parent `<rich:accordion>` component to perform an Ajax form submission, and the content of the panel is rendered. Only one panel at a time is uploaded to the client side.

**client**

Activation of a `<rich:accordionItem>` component causes the parent `<rich:accordion>` component to update on the client side. JavaScript changes the styles such that one panel component becomes hidden while the other is shown.
10.2.3. `<rich:accordion>` client-side events

In addition to the standard Ajax events and HTML events, the `<rich:accordion>` component uses the client-side events common to all switchable panels:

- The `itemchange` event points to the function to perform when the switchable item is changed.
- The `beforeitemchange` event points to the function to perform when before the switchable item is changed.

10.2.4. `<rich:accordion>` server-side events

The `<rich:accordion>` component uses the server-side events common to all switchable panels:

- The `ItemChangeEvent` event occurs on the server side when an item is changed through Ajax using the `server` mode. It can be processed using the `ItemChangeListener` attribute.

10.2.5. Reference data

- `component-type`: `org.richfaces.accordion`
- `component-class`: `org.richfaces.component.html.HtmlAccordion`
- `component-family`: `org.richfaces.accordion`
- `renderer-type`: `org.richfaces.accordionRenderer`
- `tag-class`: `org.richfaces.taglib.accordionTag`

10.2.6. `<rich:accordionItem>`

The `<rich:accordionItem>` component is a panel for use with the `<rich:accordion>` component.

10.2.6.1. Basic usage

Basic usage of the `<rich:accordionItem>` component requires the `label` attribute, which provides the text on the panel header. The panel header is all that is visible when the accordion item is collapsed.

Alternatively the `header` facet could be used in place of the `label` attribute. This would allow for additional styles and custom content to be applied to the tab.

10.2.6.2. `<rich:accordionItem>` client-side events

In addition to the standard HTML events, the `<rich:accordionItem>` component uses the client-side events common to all switchable panel items:

- The `enter` event points to the function to perform when the mouse enters the panel.
- The `leave` event points to the function to perform when the mouse leaves the panel.
10.2.6.3. Reference data

- component-type: org.richfaces.accordionItem
- component-class: org.richfaces.component.html.HtmlAccordionItem
- component-family: org.richfaces.accordionItem
- renderer-type: org.richfaces.accordionItemRenderer
- tag-class: org.richfaces.taglib.accordionItemTag

10.3. <rich:collapsiblePanel>

The <rich:collapsiblePanel> component is a collapsible panel that shows or hides content when the header bar is activated. It is a simplified version of <rich:togglePanel> component.

Figure 10.4. <rich:collapsiblePanel>

10.3.1. Basic usage

Basic usage requires the header attribute to be specified, which provides the title for the header element. Additionally the panel requires content to display when it is expanded. Content is added as child elements like a standard panel.

10.3.2. Expanding and collapsing the panel

The switching mode for performing submissions is determined by the switchType attribute, which can have one of the following three values:

server

This is the default setting. The <rich:collapsiblePanel> component performs a common submission, completely re-rendering the page. Only one panel at a time is uploaded to the client side.

ajax

The <rich:collapsiblePanel> component performs an Ajax form submission, and only the content of the panel is rendered. Only one panel at a time is uploaded to the client side.
The <rich:collapsiblePanel> component updates on the client side, re-rendering itself and any additional components listed with the render attribute.

### 10.3.3. Appearance

The appearance of the <rich:collapsiblePanel> component can be customized using facets. The headerExpandedClass and headerCollapsedClass facets are used to style the appearance of the panel when it is expanded and collapsed respectively. The expandControl facet styles the control in the panel header used for expanding, and the collapseControl facet styles the control for collapsing.

### 10.3.4. <rich:collapsiblePanel> server-side events

The <rich:collapsiblePanel> component uses the following unique server-side events:

- The ChangeExpandEvent event occurs on the server side when the <rich:collapsiblePanel> component is expanded or collapsed through Ajax using the server mode. It can be processed using the ChangeExpandListener attribute.

### 10.3.5. Reference data

- **component-type**: org.richfaces.collapsiblePanel
- **component-class**: org.richfaces.component.html.HtmlCollapsiblePanel
- **component-family**: org.richfaces.collapsiblePanel
- **renderer-type**: org.richfaces.collapsiblePanelRenderer
- **tag-class**: org.richfaces.taglib.collapsiblePanelTag

### 10.4. <rich:popupPanel>

The <rich:popupPanel> component provides a pop-up panel or window that appears in front of the rest of the application. The <rich:popupPanel> component functions either as a modal window which blocks interaction with the rest of the application while active, or as a non-modal window. It can be positioned on the screen, dragged to a new position by the user, and re-sized.

### 10.4.1. Basic usage

The <rich:popupPanel> does not require any compulsory attributes, though certain use cases require different attributes.

### 10.4.2. Showing and hiding the pop-up

If show="true" then the pop-up panel will display when the page is first loaded.
The `<rich:popupPanel>` component can be shown and hidden manually using the `show()` and `hide()` methods from the JavaScript API. These can be implemented using two different approaches:

- Using the `<rich:componentControl>` component. For details on the component, refer to Section 4.5, "<rich:componentControl>".

- Using the `rich:component` function. For details on the function, refer to Section 17.2, "rich:component".

For explicit referencing when using the functions, the component can be given an `id` identifier. The component can, however, be referenced using other means, such as through a selector.

**Example 10.2. `<rich:popupPanel>` example**

```html
<h:commandButton value="Show the panel">
     <rich:componentControl target="popup" operation="show" />
</h:commandButton>

... 

<a4j:form>
  <rich:popupPanel id="popup"/>
  
  <p><a href="#" onclick="#{rich:component('popup')}.hide()">Hide the panel</a></p>
</rich:popupPanel>
</a4j:form>
```

**Placement**

The `<rich:popupPanel>` component should usually be placed outside the original form, and include its own form if performing submissions. An exception to this is when using the `domElementAttachment` attribute, as described in Section 10.4.4, "Size and positioning".

**10.4.3. Modal and non-modal panels**

By default, the `<rich:popupPanel>` appears as a modal window that blocks interaction with the other objects on the page. To implement a non-modal window instead, set `modal="false"`. This will allow interaction with other objects outside the pop-up panel.
10.4.4. Size and positioning

The pop-up panel can be both re-sized and re-positioned by the user. The minimum possible size for the panel can be set with the `minWidth` and `minHeight` attributes. These abilities can be deactivated by setting `resizable` or `movable` to false as necessary.

The pop-up panel can be automatically sized when it is shown if the `autosized` attribute is set to true.

The `<rich:popupPanel>` component is usually rendered in front of any other objects on the page. This is achieved by attaching the component to the `<body>` element of the page, and setting a very high "z-index" (the stack order of the object). This approach is taken because relatively-positioned elements could still overlap the pop-up panel if they exist at higher levels of the DOM hierarchy, even if their z-index is less than the `<rich:popupPanel>` component. However, to avoid form limitation of the pop-up panel on pages where no such elements exist, the `<rich:popupPanel>` component can be reattached to its original DOM element by setting `domElementAttachment` to either `parent` or `form`.

Embedded objects inserted into the HTML with the `<embed>` tag will typically be rendered in front of a `<rich:popupPanel>` component. The `<rich:popupPanel>` component can be forcibly rendered in front of these objects by setting `overlapEmbedObjects = "true"`.

**Using overlapEmbedObjects**

Due to the additional script processing required when using the `overlapEmbedObjects` attribute, applications can suffer from decreased performance. As such, `overlapEmbedObjects` should only be set to true when `<embed>` tags are being used. Do not set it to true for applications that do not require it.

10.4.5. Contents of the pop-up

The `<rich:popupPanel>` component can contain any other rich component just like a normal panel.

Contents of the `<rich:popupPanel>` component which are positioned relatively may be trimmed if they extend beyond the borders of the pop-up panel. For certain in-line controls this behavior may be preferable, but for other dynamic controls it could be undesirable. If the `trimOverlayedElements` attribute is set to false then child components will not be trimmed if they extend beyond the borders of the pop-up panel.

10.4.6. Header and controls

A panel header and associated controls can be added to the `<rich:popupPanel>` component through the use of facets. The `header` facet displays a title for the panel, and the `controls` facet
can be customized to allow window controls such as a button for closing the pop-up. *Example 10.3, “Header and controls”* demonstrates the use of the facets.

**Example 10.3. Header and controls**

```xml
<h:commandLink value="Show pop-up">
    <rich:componentControl target="popup" operation="show" />
</h:commandLink>
...
<a4j:form>
<rich:popupPanel id="popup" modal="false" autosized="true" resizeable="false">
    <f:facet name="header">
        <h:outputText value="The title of the panel" />
    </f:facet>
    <f:facet name="controls">
        <h:graphicImage value="/pages/close.png" style="cursor:pointer" onclick="#{rich:component('popup')}.hide()" />
        This is the content of the panel.
    </f:facet>
</rich:popupPanel>
</a4j:form>
```
Figure 10.5. Header and controls

10.4.7. Reference data

- component-type: org.richfaces.popupPanel
- component-class: org.richfaces.component.html.HtmlpopupPanel
- component-family: org.richfaces.popupPanel
- renderer-type: org.richfaces.popupPanelRenderer
- tag-class: org.richfaces.taglib.popupPanelTag

10.5. <rich:tabPanel>

The <rich:tabPanel> component provides a set of tabbed panels for displaying one panel of content at a time. The tabs can be highly customized and themed. Each tab within a <rich:tabPanel> container is a <rich:tab> component. Refer to Section 10.5.5, "<rich:tab>" for further details on the <rich:tab> component.
Figure 10.6. A `<rich:tabPanel>` component containing three `<rich:tab>` components

Form elements required

All `<rich:tabPanel>` components should be wrapped in a form element so that the contents of the tab are processed correctly during a tab change in either `ajax` or `server` mode.

Alternatively, the contents of a `<rich:tab>` component within the `<rich:tabPanel>` component could be wrapped in a form element, such that they will be processed using the inner submitting component only. In this case, the `<rich:tabPanel>` component will automatically add form tags around the tab's contents, and the contents will not be processed during switching.

10.5.1. Switching panels

The `activeItem` attribute holds the active tab name. This name is a reference to the `name` identifier of the active child `<rich:tab>` component.

The switching mode for performing submissions is determined by the `switchType` attribute, which can have one of the following three values:

**server**

The default setting. Activation of a `<rich:tab>` component causes the parent `<rich:tabPanel>` component to perform a common submission, completely re-rendering the page. Only one tab at a time is uploaded to the client side.

**ajax**

Activation of a `<rich:tab>` component causes the parent `<rich:tabPanel>` component to perform an Ajax form submission, and the content of the tab is rendered. Only one tab at a time is uploaded to the client side.
Activation of a `<rich:tab>` component causes the parent `<rich:tabPanel>` component to update on the client side. JavaScript changes the styles such that one tab becomes hidden while the other is shown.

### 10.5.2. `<rich:tabPanel>` client-side events

In addition to the standard Ajax events and HTML events, the `<rich:tabPanel>` component uses the client-side events common to all switchable panels:

- The `itemchange` event points to the function to perform when the switchable item is changed.
- The `beforeitemchange` event points to the function to perform when before the switchable item is changed.

### 10.5.3. `<rich:tabPanel>` server-side events

The `<rich:tabPanel>` component uses the server-side events common to all switchable panels:

- The `ItemChangeEvent` event occurs on the server side when an item is changed through Ajax using the `server` mode. It can be processed using the `ItemClickListener` attribute.

### 10.5.4. Reference data

- `component-type`: `org.richfaces.tabPanel`
- `component-class`: `org.richfaces.component.html.HtmlTabPanel`
- `component-family`: `org.richfaces.tabPanel`
- `renderer-type`: `org.richfaces.tabPanelRenderer`
- `tag-class`: `org.richfaces.taglib.tabPanelTag`

### 10.5.5. `<rich:tab>`

The `<rich:tab>` component represents an individual tab inside a `<rich:tabPanel>` component, including the tab's content. Clicking on the tab header will bring its corresponding content to the front of other tabs.

#### 10.5.5.1. Basic usage

Basic usage of the `<rich:tab>` component requires the `name` attribute to uniquely identify the tab within the parent `<rich:tabPanel>` component. As the tabs are switched, the `name` identifier of the currently selected tab is stored in the `activeItem` attribute of the parent `<rich:tabPanel>` component.
10.5.5.2. Header labeling

In addition to the name identifier, the header attribute must be defined. The header attribute provides the text on the tab header. The content of the tab is then detailed inside the `<rich:tab>` tags.

Alternatively, the header facet could be used in place of the header attribute. This would allow for additional styles and custom content to be applied to the tab. The component also supports three facets to customize the appearance depending on the current state of the tab:

- **headerActiveClass facet**: This facet is used when the tab is the currently active tab.
- **headerInactiveClass facet**: This facet is used when the tab is not currently active.
- **headerDisabledClass facet**: This facet is used when the tab is disabled.

The header facet is used in place of any state-based facet that has not been defined.

10.5.5.3. Switching tabs

The switching mode for performing submissions can be inherited from the switchType attribute of the parent `<rich:tabPanel>` component, or set individually for each `<rich:tab>` component. Refer to Section 10.5, "<rich:tabPanel>" for details on the switchType attribute.

An individual tab can be disabled by setting disabled="true". Disabled tabs cannot be activated or switched to.

10.5.5.4. `<rich:tab>` client-side events

In addition to the standard HTML events, the `<rich:tab>` component uses the client-side events common to all switchable panel items:

- The enter event points to the function to perform when the mouse enters the tab.
- The leave attribute points to the function to perform when the mouse leaves the tab.

10.5.5.5. Reference data

- component-type: org.richfaces.tab
- component-class: org.richfaces.component.html.HtmlTab
- component-family: org.richfaces.tab
Chapter 10. Panels and containers

- renderer-type: org.richfaces.tabRenderer
- tag-class: org.richfaces.taglib.tabTag

10.6. `<rich:togglePanel>`

The `<rich:togglePanel>` component is a wrapper for multiple `<rich:togglePanelItem>` components. Each child component is displayed after being activated with the `<rich:toggleControl>` behavior.

Refer to Section 10.6.4, "<rich:toggleControl>" and Section 10.6, "<rich:togglePanel>" for details on how to use the components together.

The `<rich:togglePanel>` component is used as a base for the other switchable components, the `<rich:accordion>` component and the `<rich:tabPanel>` component. It provides an abstract switchable component without any associated markup. As such, the `<rich:togglePanel>` component could be customized to provide a switchable component when neither an accordion component or a tab panel component is appropriate.

10.6.1. Basic usage

The initial state of the component can be configured using the activeItem attribute, which points to a child component to display. Alternatively, if no activeItem attribute is defined, the initial state will be blank until the user activates a child component using the `<rich:toggleControl>` component.

The child components are shown in the order in which they are defined in the view.

10.6.2. Toggling between components

The switching mode for performing submissions is determined by the switchType attribute, which can have one of the following three values:

- server
  - The default setting. Activation of a child component causes the parent `<rich:togglePanel>` component to perform a common submission, completely re-rendering the page. Only one child at a time is uploaded to the client side.

- ajax
  - Activation of a child component causes the parent `<rich:togglePanel>` component to perform an Ajax form submission, and the content of the child is rendered. Only one child at a time is uploaded to the client side.

- client
  - Activation of a child component causes the parent `<rich:togglePanel>` component to update on the client side. JavaScript changes the styles such that one child component becomes hidden while the other is shown.
10.6.3. Reference data

- component-type: org.richfaces.TogglePanel
- component-class: org.richfaces.component.html.HtmlTogglePanel
- component-family: org.richfaces.TogglePanel
- renderer-type: org.richfaces.TogglePanelRenderer
- tag-class: org.richfaces.taglib.TogglePanelTag

10.6.4. `<rich:toggleControl>`

The `<rich:toggleControl>` behavior can be attached to any interface component. It works with a `<rich:togglePanel>` component to switch between different `<rich:togglePanelItem>` components.

Refer to Section 10.6, “<rich:togglePanel>” and Section 10.6.5, “<rich:togglePanelItem>” for details on how to use the components together.

10.6.4.1. Basic usage

The `<rich:toggleControl>` can be used to switch through `<rich:togglePanelItem>` components in a `<rich:togglePanel>` container. If the `<rich:toggleControl>` component is positioned inside a `<rich:togglePanel>` component, no attributes need to be defined, as the control is assumed to switch through the `<rich:togglePanelItem>` components of its parent.

A `<rich:toggleControl>` component can be located outside the `<rich:togglePanel>` component it needs to switch. Where this is the case, the `<rich:togglePanel>` is identified using the `activePanel` attribute. The Cycling through components requires the `for` attribute, which points to the `id` identifier of the `<rich:togglePanel>` that it controls.

10.6.4.2. Specifying the next state

The `<rich:toggleControl>` component will cycle through `<rich:togglePanelItem>` components in the order they are defined within the view. However, the next item to switch to can be explicitly defined by including a `<rich:toggleControl>` component within a `<rich:togglePanelItem>` and using the `targetItem` attribute. The `targetItem` attribute points to the `<rich:togglePanelItem>` to switch to when the state is next changed. Example 10.4, “<rich:toggleControl> example” demonstrates how to specify the next switchable state in this way.

Example 10.4. `<rich:toggleControl> example`

```xml
<rich:togglePanel id="layout" activeItem="short">
  <rich:togglePanelItem id="short">
    //content
  </rich:togglePanelItem>
</rich:togglePanel>
```
10.6.4.3. Reference data

- **component-type**: org.richfaces.ToggleControl
- **component-class**: org.richfaces.component.html.HtmlToggleControl
- **component-family**: org.richfaces.ToggleControl
- **renderer-type**: org.richfaces.ToggleControlRenderer
- **tag-class**: org.richfaces.taglib.ToggleControlTag

10.6.5. `<rich:togglePanelItem>`

The `<rich:togglePanelItem>` component is a switchable panel for use with the `<rich:togglePanel>` component. Switching between `<rich:togglePanelItem>` components is handled by the `<rich:toggleControl>` behavior.

10.6.5.1. Reference data

- **component-type**: org.richfaces.TogglePanelItem
- **component-class**: org.richfaces.component.html.HtmlTogglePanelItem
- **component-family**: org.richfaces.TogglePanelItem
- **renderer-type**: org.richfaces.TogglePanelItemRenderer
- **tag-class**: org.richfaces.taglib.TogglePanelItemTag
Tables and grids

Documentation in development

Some concepts covered in this chapter may refer to the previous version of Richfaces, version 3.3.3. This chapter is scheduled for review to ensure all information is up to date.

This chapter covers all components related to the display of tables and grids.

11.1. `<a4j:repeat>`

The `<a4j:repeat>` component is used to iterate changes through a repeated collection of components. It allows specific rows of items to be updated without sending Ajax requests for the entire collection. The `<a4j:repeat>` component forms the basis for many of the tabular components detailed in Chapter 11, Tables and grids.

11.1.1. Basic usage

The contents of the collection are determined using Expression Language (EL). The data model for the contents is specified with the `value` attribute. The `var` attribute names the object to use when iterating through the collection. This object is then referenced in the relevant child components. *Example 11.1, "<a4j:repeat> example"* shows how to use `<a4j:repeat>` to maintain a simple table.

**Example 11.1. `<a4j:repeat>` example**

```xml
<table>
    <tbody>
        <a4j:repeat value="#{repeatBean.items}" var="item">
            <tr>
                <td><h:outputText value="#{item.code}" id="item1" /></td>
                <td><h:outputText value="#{item.price}" id="item2" /></td>
            </tr>
        </a4j:repeat>
    </tbody>
</table>
```

Each row of a table contains two cells: one showing the item code, and the other showing the item price. The table is generated by iterating through items in the `repeatBeans.items` data model.
11.1.2. Limited views and partial updates

The `<a4j:repeat>` component uses other attributes common to iteration components, such as the `first` attribute for specifying the first item for iteration, and the `rows` attribute for specifying the number of rows of items to display.

Specific cells, rows, and columns can be updated without sending Ajax requests for the entire collection. Components that cause the change can specify which part of the table to update through the `render` attribute. The `render` attribute specifies which part of a table to update:

- `render=cellId`
  
  Update the cell with an identifier of `cellId` within the row that contains the current component.

  Instead of a specific identifier, the `cellId` reference could be a variable:
  
  `render=#(bean.cellToUpdate)`.

- `render=tableId:rowId`
  
  Update the row with an identifier of `rowId` within the table with an identifier of `tableId`. Alternatively, if the current component is contained within the table, use `render=rowId`.

  Instead of a specific identifier, the `tableId` of `rowId` references could be variables:
  
  `render=tableId:#(bean.rowToUpdate)`.

- `render=tableId:rowId:cellId`
  
  Update the cell with an identifier of `cellId`, within the row with and identifier of `rowId`, within the table with an identifier of `tableId`.

  Instead of a specific identifier, any of the references could be variables:
  
  `render=tableId:#(bean.rowToUpdate):cellId`.

Alternatively, keywords can be used with the `render` attribute:

- `render=@column`
  
  Update the column that contains the current component.

- `render=@row`
  
  Update the row that contains the current component.

- `render=tableId:@body`
  
  Update the body of the table with the identifier of `tableId`. Alternatively, if the current component is contained within the table, use `render=@body` instead.

- `render=tableId:@header`
  
  Update the header of the table with the identifier of `tableId`. Alternatively, if the current component is contained within the table, use `render=@header` instead.
update the footer of the table with the identifier of tableId. Alternatively, if the current component is contained within the table, use render-@footer instead.

11.1.3. Reference data

• component-type: org.ajax4jsf.Repeat
• component-class: org.ajax4jsf.component.html.HtmlAjaxRepeat
• component-family: javax.faces.Data
• renderer-type: org.ajax4jsf.components.RepeatRenderer

11.2. <rich:column>

The <rich:column> component facilitates columns in a table. It supports merging columns and rows, sorting, filtering, and customized skinning.

11.2.1. Basic usage

In general usage, the <rich:column> component is used in the same was as the JavaServer Faces (JSF) <h:column> component. It requires no extra attributes for basic usage, as shown in Example 11.2, “Basic column example”.

Example 11.2. Basic column example

```xml
<rich: dataTable value="# { capitalsBean.capitals }" var="cap" rows="5">
    <rich: column>
        <f: facet name="header">State Flag</f: facet>
        <h: graphicImage value="# { cap.stateFlag }"/>
    </rich: column>
    <rich: column>
        <f: facet name="header">State Name</f: facet>
        <h: outputText value="# { cap.state }"/>
    </rich: column>
    <rich: column>
        <f: facet name="header">State Capital</f: facet>
        <h: outputText value="# { cap.name }"/>
    </rich: column>
    <rich: column>
        <f: facet name="header">Time Zone</f: facet>
        <h: outputText value="# { cap.timeZone }"/>
    </rich: column>
</rich: dataTable>
```
Columns can be merged by using the `colspan` attribute to specify how many normal columns to span. The `colspan` attribute is used in conjunction with the `breakBefore` attribute on the next column to determine how the merged columns are laid out. Example 11.3, “Column spanning example”.

**Example 11.3. Column spanning example**

```xml
<rich:dataTable value="#{capitalsBean.capitals}" var="cap" rows="5">
    <rich:column colspan="3">
        <h:graphicImage value="#{cap.stateFlag}"/>
    </rich:column>
    <rich:column breakBefore="true">
        <h:outputText value="#{cap.state}"/>
    </rich:column>
    <rich:column>
        <h:outputText value="#{cap.name}"/>
    </rich:column>
    <rich:column>
        <h:outputText value="#{cap.timeZone}"/>
    </rich:column>
</rich:dataTable>
```
Similarly, the `rowspan` attribute can be used to merge and span rows. Again the `breakBefore` attribute needs to be used on related `<rich:column>` components to define the layout. Example 11.4, “Row spanning example” and the resulting Figure 11.4, “Complex headers using column groups” show the first column of the table spanning three rows.

**Example 11.4. Row spanning example**

```xml
<rich:row var="cap"
    value="# { capitalsBean.capitals }">
    <rich:column breakBefore="false">
        <f:facet name="header">State Flag</f:facet>
        <h:graphicImage value="# { cap.stateFlag }"/>
    </rich:column>
    <rich:column breakBefore="false">
        <f:facet name="header">State Info</f:facet>
        <h:outputText value="# { cap.state }"/>
    </rich:column>
    <rich:column breakBefore="false">
        <h:outputText value="# { cap.name }"/>
    </rich:column>
    <rich:column breakBefore="false">
        <h:outputText value="# { cap.timeZone }"/>
    </rich:column>
</rich:row>
```
Chapter 11. Tables and grids

Figure 11.3. Row spanning example

For details on filtering and sorting columns, refer to Section 11.9, “Table filtering” and Section 11.10, “Table sorting”.

11.2.4. Reference data

- component-type: org.richfaces.Column
- component-class: org.richfaces.component.html.HtmlColumn
- component-family: org.richfaces.Column
- renderer-type: org.richfaces.renderkit.CellRenderer
- tag-class: org.richfaces.taglib.ColumnTag

11.2.5. Style classes and skin parameters

The <rich:column> component uses the same style classes and skin parameters as the <rich: dataTable> component. Refer to Section 11.6.5, “Style classes and skin parameters” for details.
11.3. <rich:columnGroup>

The <rich:columnGroup> component combines multiple columns in a single row to organize complex parts of a table. The resulting effect is similar to using the `breakBefore` attribute of the <rich:column> component, but is clearer and easier to follow in the source code.

11.3.1. Complex headers

The <rich:columnGroup> can also be used to create complex headers in a table. Example 11.5, “Complex headers using column groups” and the resulting Figure 11.4, “Complex headers using column groups” demonstrate how complex headers can be achieved.

Example 11.5. Complex headers using column groups

```xml
<rich:columnGroup>
  <f:facet name="header">
    <rich:columnGroup>
      <rich:column <span value="=" rowspan="2">
        <h:outputText value="State Flag"/>
      </rich:column>
      <rich:column colspan="3">
        <h:outputText value="State Info"/>
      </rich:column>
      <rich:column breakBefore="true">
        <h:outputText value="State Name"/>
      </rich:column>
    </rich:columnGroup>
    <rich:column>
      <h:graphicImage value="# { cap.stateFlag }"/>
    </rich:column>
    <rich:column>
      <h:outputText value="# { cap.state }"/>
    </rich:column>
    <rich:column>
      <h:outputText value="# { cap.name }"/>
    </rich:column>
    <rich:column>
      <h:outputText value="# { cap.timeZone }"/>
    </rich:column>
  </f:facet>
</rich:columnGroup>
```

Chapter 11. Tables and grids

11.3.2. Reference data

- `component-type`: org.richfaces.ColumnGroup
- `component-class`: org.richfaces.component.html.HtmlColumnGroup
- `component-family`: org.richfaces.ColumnGroup
- `renderer-type`: org.richfaces.ColumnGroupRenderer
- `tag-class`: org.richfaces.taglib.ColumnGroupTag

11.3.3. Style classes and skin parameters

The `<rich:columnGroup>` component uses the same style classes and skin parameters as the `<rich:dataTable>` component. Refer to Section 11.6.5, “Style classes and skin parameters” for details.

11.4. `<rich:dataGrid>`

The `<rich:dataGrid>` component is used to arrange data objects in a grid. Values in the grid can be updated dynamically from the data model, and Ajax updates can be limited to specific rows. The component supports header, footer, and caption facets.

The `<rich:dataGrid>` component is similar in function to the JavaServer Faces `<h:panelGrid>` component. However, the `<rich:dataGrid>` component additionally allows iteration through the data model rather than just aligning child components in a grid layout.

---

**Figure 11.4. Complex headers using column groups**

<table>
<thead>
<tr>
<th>State Flag</th>
<th>State</th>
<th>State Capital</th>
<th>Time Zone</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Alabama</td>
<td>Montgomery</td>
<td>GMT-6</td>
</tr>
<tr>
<td></td>
<td>Alaska</td>
<td>Juneau</td>
<td>GMT-3</td>
</tr>
<tr>
<td></td>
<td>Arizona</td>
<td>Phoenix</td>
<td>GMT-7</td>
</tr>
<tr>
<td></td>
<td>Arkansas</td>
<td>Little Rock</td>
<td>GMT-6</td>
</tr>
<tr>
<td></td>
<td>California</td>
<td>Sacramento</td>
<td>GMT-8</td>
</tr>
</tbody>
</table>
11.4.1. Basic usage

The `<rich:dataGrid>` component requires the `value` attribute, which points to the data model, and the `var` attribute, which holds the current variable for the collection of data.

11.4.2. Customizing the grid

The number of columns for the grid is specified with the `columns` attribute, and the number of elements to layout among the columns is determined with the `elements` attribute. The `first` attribute references the zero-based element in the data model from which the grid starts.

Example 11.6. `<rich:dataGrid>` example

```xml
<rich:panel style="width:150px;height:200px;"
  
  <h:form>
    <rich:dataGrid value="#{dataTableScrollerBean.allCars}" var="car" columns="2" elements="4" first="1">
      <f:facet name="header">
        <h:outputText value="Car Store"/>
      </f:facet>
      <rich:panel>
        <f:facet name="header">
          <h:outputText value="#{car.make} #{car.model}"/>
        </f:facet>
        <h:panelGrid columns="2">
          <h:outputText value="Price:" styleClass="label"/>
          <h:outputText value="#{car.price}"/>
          <h:outputText value="Mileage:" styleClass="label"/>
          <h:outputText value="#{car.mileage}"/>
        </h:panelGrid>
      </rich:panel>
    </rich:dataGrid>
  </h:form>
</rich:panel>
```
11.4.3. Partial updates

As `<rich:dataGrid>` the component is based on the `<a4j:repeat>` component, it can be partially updated with Ajax. Refer to Section 11.1.2, “Limited views and partial updates” for details on partially updating the `<rich:dataGrid>` component.

11.4.4. Reference data

- `component-type`: `org.richfaces.DataGrid`
- `component-class`: `org.richfaces.component.html.HtmlDataGrid`
- `component-family`: `org.richfaces.DataGrid`
- `renderer-type`: `org.richfaces.DataGridRenderer`
- `tag-class`: `org.richfaces.taglib.DataGridTag`
11.4.5. Style classes and skin parameters

The `<rich:dataGrid>` component uses the same style classes and skin parameters as the `<rich:dataTable>` component. Refer to Section 11.6.5, “Style classes and skin parameters” for details.

11.5. `<rich:dataScroller>`

The `<rich:dataScroller>` component is used for navigating through multiple pages of tables or grids.

![Rich dataScroller component](image)

**Figure 11.7.** The `<rich:dataScroller>` component

11.5.1. Basic usage

The `<rich:dataScroller>` must be placed in the footer facet of the table or grid it needs to control. Alternatively, use the `for` attribute to bind the parent table or grid to the scroller.

The bound table or grid should also have the `rows` attribute defined to limit the number of rows per page.

The `<rich:dataScroller>` component must be re-rendered whenever a filter changes on the bound table, so that the scroller matches the current model for the table.

**Example 11.7. Basic usage**

```xml
<rich:dataTable id="table" value="# { capitalsBean.capitals }" var="cap" rows="5">
  <!-- table content -->
</rich:dataTable>
```
11.5.2. Appearance and interactivity

The page attribute is a value-binding attribute used to define and save the current page number.

The <rich:dataScroller> component provides a range of controllers for scrolling through tables and grids:

Controls for scrolling by a specific amount

The component includes controls for switching to the first page, the last page, the next page, and the previous page, as well as controls for fast-forwarding or rewinding by a set amount. Use the fastStep attribute to set the number of pages to skip when fast-forwarding or rewinding.

The appearance of these controls can be customized using the following facets: first, last, next, previous, fastforward, and rewind. Additionally, there are facets for the controls' disabled states: first_disabled, last_disabled, next_disabled, previous_disabled, fastforward_disabled, and rewind_disabled.

Page controls

The component also features a series of numbered controls to jump to a specific page. Use the maxPages attribute to limit the number of page controls that appear. The current page control is highlighted.

The pageIndexVar and pagesVar attributes are request-scope variables for the current page and the total number of pages. Use these attributes with the pages facet to provide information about the pages of the table, as shown in Example 11.8, “pages facet”.

Example 11.8. pages facet
To add optional separators between controls, define the separators with the `controlsSeparator` facet.

### 11.5.3. Reference data

- `component-type`: `org.richfaces.DataScroller`
- `component-class`: `org.richfaces.component.html.HtmlDataScroller`
- `component-family`: `org.richfaces.DataScroller`
- `renderer-type`: `org.richfaces.DataScrollerRenderer`
- `tag-class`: `org.richfaces.taglib.DataScrollerTag`

### 11.6. `<rich:dataTable>`

The `<rich:dataTable>` component is used to render a table, including the table's header and footer. It works in conjunction with the `<rich:column>` and `<rich:columnGroup>` components to list the contents of a data model.

The `<rich:dataTable>` component does not include extended table features, such as data scrolling, row selection, and column reordering. These features are available as part of the `<rich:extendedDataTable>` component; refer to Section 11.7, “<rich:extendedDataTable>” for further details.

#### 11.6.1. Basic usage

The `value` attribute points to the data model, and the `var` attribute specifies a variable to use when iterating through the data model.

#### 11.6.2. Customizing the table

The `first` attribute specifies which item in the data model to start from, and the `rows` attribute specifies the number of items to list. The `header`, `footer`, and `caption` facets can be used to
display text, and to customize the appearance of the table through skinning. demonstrates a simple table implementation.

Example 11.9. `<rich:dataTable> example

```
<rich:dataTable value="#{capitalsBean.capitals}" var="cap" rows="5">
  <f:facet name="caption">
    <h:outputText value="United States Capitals" />
  </f:facet>
  <f:facet name="header">
    <h:outputText value="Capitals and States Table" />
  </f:facet>
  <rich:column>
    <f:facet name="header">State Flag</f:facet>
    <h:graphicImage value="#{cap.stateFlag}"/>
    <f:facet name="footer">State Flag</f:facet>
  </rich:column>
  <rich:column>
    <f:facet name="header">State Name</f:facet>
    <h:outputText value="#{cap.state}"/>
    <f:facet name="footer">State Name</f:facet>
  </rich:column>
  <rich:column>
    <f:facet name="header">State Capital</f:facet>
    <h:outputText value="#{cap.name}"/>
    <f:facet name="footer">State Capital</f:facet>
  </rich:column>
  <rich:column>
    <f:facet name="header">Time Zone</f:facet>
    <h:outputText value="#{cap.timeZone}"/>
    <f:facet name="footer">Time Zone</f:facet>
  </rich:column>
  <f:facet name="footer">
    <h:outputText value="Capitals and States Table" />
  </f:facet>
</rich:dataTable>
```
11.6.3. Partial updates

As `<rich:dataTable>` the component is based on the `<a4j:repeat>` component, it can be partially updated with Ajax. Refer to Section 11.1.2, “Limited views and partial updates” for details on partially updating the `<rich:dataTable>` component.

11.6.4. Reference data

- `component-type: org.richfaces.DataTable`
- `component-class: org.richfaces.component.html.HtmlDataTable`
- `component-family: org.richfaces.DataTable`
- `renderer-type: org.richfaces.DataTableRenderer`
- `tag-class: org.richfaces.taglib.DataTableTag`

11.6.5. Style classes and skin parameters

Table 11.1. Style classes (selectors) and corresponding skin parameters

<table>
<thead>
<tr>
<th>Class (selector)</th>
<th>Skin Parameters</th>
<th>Mapped CSS properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>.rich-table</td>
<td>tableBackgroundColor</td>
<td>background-color</td>
</tr>
</tbody>
</table>

This class defines the styles for a table.
<table>
<thead>
<tr>
<th>Class (selector)</th>
<th>Skin Parameters</th>
<th>Mapped CSS properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>.rich-table-cell</td>
<td>generalSizeFont</td>
<td>font-size</td>

<tr>
<td>.rich-table-subheader</td>
<td>additionalBackgroundColor</td>
<td>background-color</td>
</tr>
<tr>
<td>.rich-table-thead</td>
<td>tableBorderWidth,</td>
<td>border-bottom</td>
</tr>
<tr>
<td></td>
<td>tableBorderColor</td>
<td></td>
</tr>
<tr>
<td>.rich-table-subheadercell</td>
<td>tableBorderColor</td>
<td></td>
</tr>
<tr>
<td>.rich-table-subheadercell</td>
<td>tableBorderColor</td>
<td></td>
</tr>
<tr>
<td>.rich-table-footer</td>
<td>tableFooterBackgroundColor</td>
<td>background-color</td>
</tr>
</tbody>
</table>
### Class (selector) | Skin Parameters | Mapped CSS properties
---|---|---
.rich-table-footer-continue | tableFooterBackgroundColor | background-color
This class defines the styles for all footer lines after the first.

.rich-table-footercell | tableBorderWidth, tableBorderColor | border-right, border-bottom
This class defines styles for a footer cell.

generalTextColor | color

headerWeightFont | font-weight

generalSizeFont | font-size

generalFamilyFont | font-family

.rich-table-subfooter | tableSubfooterBackgroundColor | background-color
This class defines the styles for a column footer.

.rich-table-subfootercell | tableBorderWidth, tableBorderColor | border-right, border-bottom
This class defines the styles for a column footer cell.

generalTextColor | color

generalSizeFont | font-size

generalFamilyFont | font-family

.rich-table-row | No skin parameters.
This class defines styles for a table row.

.rich-table-firstrow | No skin parameters.
This class defines styles for a table's first row.

.rich-table-caption | No skin parameters.
This class defines styles for a "caption" facet element.

### 11.7. `<rich:extendedDataTable>`

The `<rich:extendedDataTable>` component builds on the functionality of the `<rich:dataTable>` component, adding features such as data scrolling, row and column selection, and rearranging of columns.

The `<rich:extendedDataTable>` component includes the following attributes not included in the `<rich:dataTable>` component:

- frozenColumns
Chapter 11. Tables and grids

- height
- noDataLabel
- onselectionchange
- selectedClass
- selection
- selectionMode
- tableState

The `<rich:extendedDataTable>` component does not include the following attributes available with the `<rich:dataTable>` component:

- columns
- columnsWidth

11.7.1. Basic usage

Basic use of the `<rich:extendedDataTable>` component requires the `value` and `var` attributes, the same as with the `<rich:dataTable>` component. Refer to Section 11.6, `<rich:dataTable>` for details.

11.7.2. Table appearance

The `height` attribute defines the height of the table on the page. This is set to 100% by default. The width of the table can be set by using the `width` attribute. As with the `<rich:dataTable>` component, the look of the `<rich:extendedDataTable>` component can be customized and skinned using the header, footer, and caption facets.

11.7.3. Extended features

Example 11.10. `<rich:extendedDataTable>` example

```html
<rich:extendedDataTable id="edt" value="#{extendedDT.dataModel}" var="edt" width="500px" height="500px">
    <rich:column id="id" headerClass="dataTableHeader" width="50" label="Id" sortBy="#{edt.id}"
                 filterBy="#{edt.name}" filterEvent="keyup"
                 visible="false">
        <f:facet name="header">
            <h:outputText value="Id" />
        </f:facet>
        <h:outputText value="#{edt.id}" />
    </rich:column>

    <rich:column id="name" width="300" headerClass="dataTableHeader" label="Name" sortBy="#{edt.name}"
                 visible="false">
        <f:facet name="header">
```

```html
```
Example 11.10, "<rich:extendedDataTable> example" shows an example extended data table. The implementation features a scrolling data table, selection of one or more rows, sorting by columns, grouping by column, and a filter on the Name column.
11.7.3.1. Row selection

Row selection is determined by the selectionMode attribute. Setting the attribute to none allows for no row selection capability. Setting the selectionMode attribute to single allows the user to select a single row at a time using the mouse. With the selectionMode attribute set to multi, the user can select multiple rows by holding down the Shift or Ctrl keys while clicking. The selection attribute points to the object that tracks which rows are selected. Figure 11.10, “Selecting multiple rows” shows the table from the example with multiple rows selected.

<table>
<thead>
<tr>
<th>Id</th>
<th>Name</th>
<th>Date</th>

</tr>
</tbody>
</table>

Figure 11.10. Selecting multiple rows

11.7.3.2. Filtering

The example table features a text field as part of the header of a column. A user can type their criteria into the text field to customize the filter of the column below. For full details on filtering tables, refer to Section 11.9, “Table filtering”.

11.7.3.3. Sorting

The example table features controls in the column headers for sorting the the table according to the relevant column. The value of the data model to sort by is specified with the sortBy attribute. For full details on sorting tables, refer to Section 11.10, “Table sorting”.

11.7.3.4. Rearranging columns

Columns in a <rich:extendedDataTable> component can be rearranged by the user by dragging each column to a different position. The label attribute for the <rich:column> component is displayed during dragging, as shown in
11.7.3.5. Saving the state

Once the contents of the table have been rearranged and customized by the user, the `tableState` attribute can be used to preserve the customization so it can be restored later. The `tableState` attribute points to a backing-bean property which can in turn be saved to a database separate from standard JSF state-saving mechanisms.

11.7.4. Reference data

- `component-type`: `org.richfaces.ExtendedDataTable`
- `component-class`: `org.richfaces.component.html.HtmlExtendedDataTable`
- `component-family`: `org.richfaces.ExtendedDataTable`
- `renderer-type`: `org.richfaces.ExtendedDataTableRenderer`

11.8. `<rich:list>`

The `<rich:list>` component renders a list of items. The list can be an numerically ordered list, an un-ordered bullet-point list, or a data definition list. The component uses a data model for managing the list items, which can be updated dynamically.

11.8.1. Basic usage

The `var` attribute names a variable for iterating through the items in the data model. The items to iterate through are determined with the `value` attribute by using EL (Expression Language).

11.8.2. Type of list

By default, the list is displayed as an un-ordered bullet-point list. The `type` attribute is used to specify different list types:

unordered

The default presentation. The list is presented as a series of bullet-points, similar to the `<ul>` HTML element.

   Price: 51555
   Mileage: 51549.0

Figure 11.13. Ordered list

definitions

The list is presented as a series of data definitions. Part of the data model, specified as the term, is listed prominently. The other associated data is listed after each term.

Example 11.11. Data definition list

```html
<h:form>
  <rich:list var="car" value="#{dataTableScrollerBean.allCars}" type="definitions" rows="5">
    <f:facet name="term">
      <h:outputText value="#{car.make} #{car.model}"/>
    </f:facet>
    <h:outputText value="Price:" styleClass="label"/>
  </rich:list>
</h:form>
```

Figure 11.14. Data definition list

The term is marked using the term facet. The facet is required for all definition lists. Use of the facet is shown in Example 11.11, “Data definition list”.

Example 11.11. Data definition list
11.8.3. Bullet and numeration appearance

The appearance of bullet points for unordered lists or numeration for ordered lists can be customized through CSS, using the list-style-type property.

11.8.4. Customizing the list

The first attribute specifies which item in the data model to start from, and the rows attribute specifies the number of items to list. The title attribute is used for a floating tool-tip. Example 11.12, "<rich:list> example" shows a simple example using the <rich:list> component.

Example 11.12. <rich:list> example

```
<h:form>
  <rich:list var="car" value="#{dataTableScrollerBean.allCars}" rows="5" type="unordered" title="Car Store">
    <h:outputText value="#{car.make} #{car.model}" /><br/>
    <h:outputText value="#{car.price}" styleClass="label" /><br/>
    <h:outputText value="Mileage: #{car.mileage}" /><br/>
  </rich:list>
</h:form>
```

</table>

11.9. Table filtering

Documentation in development

This section is currently under development. Any features it describes may not be available in the current release of RichFaces.

Tables entries can be filtered by the user through either the basic method built in to the `<rich:column>` component, or by defining external filters. Refer to Section 11.2, “<rich:column>” for details on using the `<rich:column>` component in tables.

11.9.1. Basic filtering

The built-in filtering abilities of the `<rich:column>` component allow the user to enter text as a filtering value. The table displays only those entries that begin with the filter value.

Set the `filterValue` attribute to point to the value used to filter the column. This can be either an initial filtering value on the page, or a value binding on the server. The `filterValue` value
is then used with the JavaScript `startsWith()` method to filter the column entries based on the data specified with the `filterBy` attribute. Expressions in the `filterBy` attribute must refer to the variable declared in the table’s `var` attribute, which is used to fill the contents of the table.

The filter is processed and the table is rendered when the `onblur` event occurs for the column. This can be changed by defining a different event with the `filterEvent` attribute. For example, to implement live updating such that the filter refreshes after every keystroke, set `filterEvent="keyup"`.

**Example 11.13. Basic filtering**

```xml
<rich:dataTable value="#{capitalsBean.capitals}" var="cap">
  <f:facet name="header">
    <rich:column>
      <h:outputText value="State Name"/>
    </rich:column>
    <rich:column>
      <h:outputText value="State Capital"/>
    </rich:column>
  </f:facet>
  <rich:column filterValue="#{capitalsBean.currentStateFilterValue}"
               filterBy="#{cap.state}" filterEvent="keyup">
    <h:outputText value="#{cap.state}"/>
  </rich:column>
  <rich:column filterValue="#{capitalsBean.currentNameFilterValue}"
               filterBy="#{cap.name}" filterEvent="keyup">
    <h:outputText value="#{cap.name}"/>
  </rich:column>
</rich:dataTable>
```

The example uses the basic filtering method on both columns in the table.

<table>
<thead>
<tr>
<th>State Name</th>
<th>State Capital</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nebraska</td>
<td>Lincoln</td>
</tr>
<tr>
<td>Nevada</td>
<td>Carson City</td>
</tr>
<tr>
<td>New Hampshire</td>
<td>Concord</td>
</tr>
<tr>
<td>New Jersey</td>
<td>Trenton</td>
</tr>
<tr>
<td>New Mexico</td>
<td>Santa Fe</td>
</tr>
<tr>
<td>New York</td>
<td>Albany</td>
</tr>
<tr>
<td>North Carolina</td>
<td>Raleigh</td>
</tr>
<tr>
<td>North Dakota</td>
<td>Bismarck</td>
</tr>
</tbody>
</table>
11.9.2. External filtering

If you require more advanced filtering using custom functions or expressions, use the external filtering properties of the <rich:column> component.

Use the filterExpression attribute to define an expression that can be evaluated as a boolean value. The expression checks if each table entry satisfies the filtering condition when the table is rendered.

Use the filterMethod attribute to define a method binding. The method needs to accept an object as a parameter and return a boolean value. Similar to the filterExpression attribute, the table is rendered only with those entries that satisfy the filtering condition. By defining a custom filtering method, you can implement complex business logic to filter a table.

Example 11.14. External filtering

```xml
<rich:dataTable value="#{capitalsBean.capitals}" var="cap" id="table">
    <f:facet name="header">
        <rich:column>
            <h:outputText value="State Name"/>
        </rich:column>
        <rich:column>
            <h:outputText value="State Time Zone"/>
        </rich:column>
    </f:facet>
</rich:column>

    <f:facet name="header">
        <rich:column filterMethod="#{filteringBean.filterStates}">
            <f:facet name="header">
                <h:selectOneMenu value="#{filteringBean.filterZone}"
                     <f:selectItems value="#{filteringBean.filterZones}"/>  
                <a4j:ajax event="change" render="table"  
                        ignoreDupResponses="true" requestDelay="700"/>
            </f:facet>
        </rich:column>
        <h:outputText value="#{cap.state}"/>
    </f:facet>
</rich:dataTable>
```

The example uses a filter expression on the first column and a filter method on the second column.
Tables entries can be sorted by defining external sorting algorithms. Refer to Section 11.2, "<rich:column>" for details on using the <rich:column> component in tables.

**Sorting non-English tables**

To sort a table whose contents are not in English, add the org.richfaces.datatableUsesViewLocale context parameter to the project’s web.xml settings file. Set the value of the context parameter to true.

### 11.10.1. External sorting

Bind the sortOrder attribute to bean properties to manage the sorting order externally. The bean must handle all the sorting algorithms. Example 11.15, “External sorting” demonstrates table sorting using an external control.

**Example 11.15. External sorting**

```xml
<rich:dataTable value="#{dataTableScrollerBean.allCars}" var="category" rows="20" id="table" reRender="ds2"
sortPriority="#{sortingBean.prioritList}"
>
  <rich:column id="make" sortBy="#{category.make}"
sortBy="# {category.make}"
>
    <f:facet name="header">
      <h:outputText styleClass="headerText" value="Make" />
    </f:facet>
    <h:outputText value="# {category.make}" />
  </rich:column>
  <rich:column id="model" sortBy="#{category.model}"
sortBy="# {category.model}"
>
The example uses an external control to manage the table's sorting.

<table>
<thead>
<tr>
<th>Make</th>
<th>Model</th>
<th>Price</th>
<th>Mileage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chevrolet</td>
<td>Corvette</td>
<td>21227</td>
<td>32762.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Corvette</td>
<td>26659</td>
<td>14208.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Corvette</td>
<td>45779</td>
<td>24349.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Malibu</td>
<td>15708</td>
<td>74154.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Malibu</td>
<td>54037</td>
<td>71257.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Malibu</td>
<td>39546</td>
<td>31674.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>S-10</td>
<td>21599</td>
<td>39670.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>S-10</td>
<td>18042</td>
<td>65112.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>S-10</td>
<td>42583</td>
<td>22633.0</td>
</tr>
</tbody>
</table>

When using the sortMode="multiple" configuration, set the priority by which columns are sorted with the sortPriorities attribute.

Use the sortExpression attribute to define a bean property to use for sorting the column. The expression checks each table entry against the sorting expression during rendering.
Chapter 12.

Trees

Documentation in development

Some concepts covered in this chapter may refer to the previous version of Richfaces, version 3.3.3. This chapter is scheduled for review to ensure all information is up to date.

Read this chapter for details on components that use tree structures.

12.1. <rich:tree>

The <rich:tree> component provides a hierarchical tree control. Each <rich:tree> component typically consists of <rich:treeNode> child components. The appearance and behavior of the tree and its nodes can be fully customized.

12.1.1. Basic usage

The <rich:tree> component requires the value attribute to point to the data model for populating the tree. The data model must be either an org.richfaces.model.TreeNode interface, an org.richfaces.model.TreeDataModel interface, or a javax.swing.tree.TreeNode interface. The var attribute declares the variable used for iterating through the data model, so that child <rich:treeNode> components can reference each iteration.

Ideally, the <rich:tree> component needs one or more <rich:treeNode> components to work with the data model. However if no <rich:treeNode> components are provided the tree creates default nodes instead.

Example 12.1. Basic usage

This example demonstrates basic usage of the <rich:tree> component using an org.richfaces.model.TreeNode data model.

The data model is constructed as follows:

```java
private TreeNodeImpl<String> stationRoot = new TreeNodeImpl<String>();
private TreeNodeImpl<String> stationNodes = new TreeNodeImpl<String>();
private String[] kickRadioFeed = { "Hall & Oates - Kiss On My List",
                                   "David Bowie - Let's Dance",
                                   "Lyn Collins - Think (About It)",
                                   "Kim Carnes - Bette Davis Eyes",
                                   "KC & the Sunshine Band - Give It Up"};
```
stationRoot.setData("KickRadio");
stationNodes.addChild(0, stationRoot);
for (int i = 0; i < kickRadioFeed.length; i++){
    TreeNodeImpl<String> child = new TreeNodeImpl<String>();
    child.setData(kickRadioFeed[i]);
    stationRoot.addChild(i, child);
}

The tree then accesses the nodes of the model using the station variable:

```xml
<rich:tree value="#{stations.stationNodes}" var="station">
    <rich:treeNode>
        <h:outputText value="#{station}" />  
    </rich:treeNode>
</rich:tree>
```

12.1.2. Appearance

Different nodes in the tree can have different appearances, such as node icons, depending on the type of data the node contains. Use the nodeType attribute to differentiate the types of nodes; the node is then rendered according to the <rich:treeNode> component with the corresponding type attribute. Example 12.2, “nodeType attribute” shows a <rich:tree> component with three different child <rich:treeNode> components defined to represent three different node appearances. Refer to Section 12.1.8.2, “Appearance” for details on customizing the appearance of <rich:treeNode> components.

Example 12.2. nodeType attribute

```xml
<rich:tree style="width:300px" value="#{library.data}" var="item" nodeType="#{item.type}">
    <rich:treeNode type="artist" iconLeaf="/images/tree/singer.png">
        <h:outputText value="#{item.name}" />  
    </rich:treeNode>
    <rich:treeNode type="album" iconLeaf="/images/tree/disc.png">
        <h:outputText value="#{item.title}" />  
    </rich:treeNode>
    <rich:treeNode type="song" iconLeaf="/images/tree/song.png">
        <h:outputText value="#{item.title}" />  
    </rich:treeNode>
</rich:tree>
```
Alternatively, use Expression Language (EL) with the `nodeType` attribute, as shown in Example 12.3, "nodeType attribute with Expression Language".

**Example 12.3. nodeType attribute with Expression Language**

```xml
<rich:tree value="#{library.data}" var="item"
    nodeType="#{data.name != 'param-value' ? 'artist' : 'album'}">
```

If the `nodeType` attribute returns null, the node is rendered as a "typeless" (or default) node. The *typeless* node is the first child `<rich:treeNode>` component with a valid `rendered` attribute, but without a defined `type` attribute.

If the `nodeType` attribute is not included and there are no child `<rich:treeNode>` components, the tree constructs a default node itself.

Icons for different nodes and node states can be defined for the whole tree using the following attributes:

### iconLeaf

The `iconLeaf` attribute points to the icon to use for any node that does not contain any child nodes.

### iconExpanded and iconCollapsed

The `iconExpanded` and `iconCollapsed` attributes point to the icons to use for expanded and collapsed nodes respectively. If these attributes are defined, the `icon` attribute is not used.

**12.1.3. Expanding and collapsing tree nodes**

The mode for performing submissions when nodes are expanded or collapsed is determined by the `toggleType` attribute, which can have one of the following three values:
ajax
This is the default setting. The `<rich:tree>` component performs an Ajax form submission, and only the content of the tree is rendered.

server
The `<rich:tree>` component performs a common submission, completely re-rendering the page.

client
The `<rich:tree>` component updates on the client side, re-rendering itself and any additional components listed with the `render` attribute.

By default, the event to expand or collapse a tree node is a mouse click. To specify a different event, use the `toggleNodeEvent` attribute.

### 12.1.4. Selecting tree nodes

The mode for performing submissions when nodes are selected is determined by the `selectionType` attribute, which can have one of the following three values:

ajax
This is the default setting. The `<rich:tree>` component performs an Ajax form submission, and only the content of the tree is rendered.

server
The `<rich:tree>` component performs a common submission, completely re-rendering the page.

client
The `<rich:tree>` component updates on the client side, re-rendering itself and any additional components listed with the `render` attribute.

### 12.1.5. Identifying nodes

The `<rich:tree>` component uses a data model to represent the node structure on the page. To identify a particular node during a client request, the model provides unique keys for tree nodes. The `<rich:tree>` component can use strings as key values. These strings may contain special characters that are not allowed by browsers, such as the left angle bracket (<) and ampersand (&). To allow these characters in the keys, the following converter is provided:

```java
org.richfaces.TreeRowKeyConverter
```

The `org.richfaces.TreeRowKeyConverter` converter is used for trees constructed using `<rich:treeNode>` components. The key should be of the type `java.lang.String`.

To apply a converter to the `<rich:tree>` component, define it with the `rowKeyConverter` attribute. `Example 12.4, “Identifying nodes”` demonstrates the use of a converter to identify tree nodes.
Example 12.4. Identifying nodes

```
<rich:tree value="#{treeBean.data}" var="node"
    rowKeyConverter="org.richfaces.TreeRowKeyConverter">
    <rich:treeNode>
        <h:outputText value="#{node}"/>
    </rich:treeNode>
</rich:tree>
```

The tree uses the following data model. The model can contain special characters normally disallowed in web page code.

```java
String[] components = {"<a4j:keepAlive >","< a4j:actionParam >"};
String[] attributes = {{"ajaxOnly", "beanName"},
                        {"name", "value", "assignTo"}};

data = new TreeNodeImpl<String>();

for (int i = 0; i < components.length; i++) {
    TreeNode<String> child = new TreeNodeImpl<String>();
    child.setData(components[i]);
    data.addChild(components[i], child);

    for (int j = 0; j < attributes[i].length; j++) {
        TreeNode<String> grandChild = new TreeNodeImpl<String>();
        grandChild.setData(attributes[i][j]);
        child.addChild(attributes[i][j], grandChild);
    }
}
```

12.1.6. Event handling

In addition to the standard Ajax events and HTML events, the `<rich:tree>` component uses the following client-side events:

- The `nodetoggle` event is triggered when a node is expanded or collapsed.
- The `beforenodetoggle` event is triggered before a node is expanded or collapsed.
- The `selectionchange` event is triggered when a node is selected.
- The `beforeselectionchange` event is triggered before a node is selected.

The `<rich:tree>` component uses the following server-side listeners:

- The `toggleListener` listener processes expand and collapse events.
• The `selectionChangeListener` listener processes the request when a node is selected.

### 12.1.7. Reference data

- `component-type`: `org.richfaces.tree`
- `component-class`: `org.richfaces.component.html.Htmltree`
- `component-family`: `org.richfaces.tree`
- `renderer-type`: `org.richfaces.treeRenderer`
- `tag-class`: `org.richfaces.taglib.treeTag`

### 12.1.8. `<rich:treeNode>`

The `<rich:treeNode>` component is a child component of the `<rich:tree>` component. It represents nodes in the parent tree. The appearance and functionality of each tree node can be customized.

#### 12.1.8.1. Basic usage

The `<rich:treeNode>` component must be a child of a `<rich:tree>` component. It does not need any attributes declared for basic usage, but can provide markup templates for tree nodes of particular types. Refer to Example 12.1, "Basic usage" for an example of basic `<rich:treeNode>` component usage.

#### 12.1.8.2. Appearance

Refer to Section 12.1.2, "Appearance" for the `<rich:tree>` component for details and examples on styling nodes and icons. Icon styling for individual `<rich:treeNode>` components uses the same attributes as the parent `<rich:tree>` component: `iconLeaf`, `iconExpanded`, and `iconCollapsed`. Icon-related attributes specified for child `<rich:treeNode>` components overwrite any global icon attributes of the parent `<rich:tree>` component.

Use the `rendered` attribute to determine whether the node should actually be rendered in the tree or not. Using the `rendered` attribute in combination with the `<rich:treeNode>` type attribute can allow further style differentiation between node content, as shown in Example 12.5, "rendered attribute".

#### Example 12.5. rendered attribute

The `rendered` attribute is used to differentiate between music albums that are in stock and those that are not. The `item` attributes return values that are otherwise identical; only the `item.exist` property differs, so it is used for the `rendered` attribute.

```xml
<rich:tree style="width:300px" value="#(library.data)"
          var="item" nodeFace="#{item.type}"
```
12.1.8.3. Interactivity

Interactivity with individual nodes, such as expanding, collapsing, and other event handling, can be managed by the parent `<rich:tree>` component. Refer to Section 12.1.3, “Expanding and collapsing tree nodes” and Section 12.1.6, “Event handling” for further details.

Use the expanded attribute to determine whether the node is expanded or collapsed.

12.1.8.4. Reference data

- component-type: org.richfaces.treeNode
- component-class: org.richfaces.component.html.HtmltreeNode
- component-family: org.richfaces.treeNode
- renderer-type: org.richfaces.treeNodeRenderer
- tag-class: org.richfaces.taglib.treeNodeTag

12.2. Tree adaptors

Use a tree adaptor to create a tree and populate it with data from a defined data model.
12.2.1. `<rich:treeModelAdaptor>`

The `<rich:treeModelAdaptor>` component takes a defined data model and uses it to populate an associated `<rich:tree>` component.

12.2.1.1. Basic usage

The `<rich:treeModelAdaptor>` component is added as a nested child component to the `<rich:tree>` component it will populate.

The `<rich:treeModelAdaptor>` component requires the `nodes` attribute for basic usage. The `nodes` attribute defines a collection of elements to iterate through for populating the tree.

12.2.1.2. Multiple levels

`<rich:treeModelAdaptor>` components can further be nested in other `<rich:treeModelAdaptor>` components to subsequently populate lower levels of the tree.

Use the `var` attribute to access the current collection element at each level. Example 12.6, “Nested `<rich:treeModelAdaptor>` components” demonstrates a series of nested `<rich:treeModelAdaptor>` components, each using the parent's `var` attribute to reference the current element.

Example 12.6. Nested `<rich:treeModelAdaptor>` components

```xml
<rich:tree>
  <rich:treeNodesAdaptor id="project" nodes="#{loaderBean.projects}" var="project">
    <rich:treeNode>
      <h:commandLink action="#{project.click}" value="Project: #{project.name}" />
    </rich:treeNode>
  </rich:treeNodesAdaptor>

  <rich:treeNodesAdaptor id="srcDir" var="srcDir" nodes="#{project.srcDirs}">
    <rich:treeNode>
      <h:commandLink action="#{srcDir.click}" value="Source directory: #{srcDir.name}" />
    </rich:treeNode>
  </rich:treeNodesAdaptor>

  <rich:treeNodesAdaptor id="pkg" var="pkg" nodes="#{srcDir.packages}">
    <rich:treeNode>
      <h:commandLink action="#{pkg.click}" value="Package: #{pkg.name}" />
    </rich:treeNode>
  </rich:treeNodesAdaptor>

  <rich:treeNodesAdaptor id="class" var="class" nodes="#{pkg.classes}">
    <rich:treeNode>
      <h:commandLink action="#{class.click}" value="Class: #{class.name}" />
    </rich:treeNode>
  </rich:treeNodesAdaptor>
</rich:tree>
```
12.2.1.3. Reference data

- component-type: org.richfaces.treeModelAdaptor
- component-class: org.richfaces.component.html.HtmltreeModelAdaptor
- component-family: org.richfaces.treeModelAdaptor
- tag-class: org.richfaces.taglib.treeModelAdaptorTag

12.2.2. <rich:treeModelRecursiveAdaptor>

The <rich:treeModelRecursiveAdaptor> component recursively populates a tree with hierarchical nodes, such as for a file system with multiple levels of directories and files.

12.2.2.1. Basic usage

The <rich:treeModelRecursiveAdaptor> component is an extension of the <rich:treeModelAdaptor> component. As such, the <rich:treeModelRecursiveAdaptor> component uses all of the same attributes. Refer to Section 12.2.1, "<rich:treeModelAdaptor>" for details on the <rich:treeModelAdaptor> component.

In addition, the <rich:treeModelRecursiveAdaptor> component requires the root attribute. The root attribute defines the collection to use at the top of the recursion. For subsequent levels, the node attribute is used for the collection.

Example 12.7, “Basic usage” demonstrates how the <rich:treeModelRecursiveAdaptor> component can be used in conjunction with the <rich:treeModelAdaptor> component to recursively iterate through a file system and create a tree of directories and files.

Example 12.7. Basic usage

```xml
<rich:tree var="item">
  <rich:treeModelRecursiveAdaptor roots="# {fileSystemBean.sourceRoots} " nodes="# {item.directories} ">
    <rich:treeNode>
      # {item.shortPath}
    </rich:treeNode>
    <rich:treeModelAdaptor nodes="# {item.files} ">
      <rich:treeNode>
        # {item}
      </rich:treeNode>
    </rich:treeModelAdaptor>
  </rich:treeModelRecursiveAdaptor>
</rich:tree>
```
12.2.2.2. Reference data

- component-type: org.richfaces.treeModelRecursiveAdaptor
- component-class: org.richfaces.component.html.HtmltreeModelRecursiveAdaptor
- component-family: org.richfaces.treeModelRecursiveAdaptor
- tag-class: org.richfaces.taglib.treeModelRecursiveAdaptorTag
Chapter 13.

Menus and toolbars

Documentation in development

Some concepts covered in this chapter may refer to the previous version of Richfaces, version 3.3.3. This chapter is scheduled for review to ensure all information is up to date.

Read this chapter for details on menu and toolbar components.

13.1. <rich:dropDownMenu>

The <rich:dropDownMenu> component is used for creating a drop-down, hierarchical menu. It can be used with the <rich:toolbar> component to create menus in an application’s toolbar.

![Figure 13.1. <rich:dropDownMenu>]

13.1.1. Basic usage

The <rich:dropDownMenu> component only requires the label attribute for basic usage. Use the label attribute to define the text label that appears as the title of the menu. Clicking on the title drops the menu down.

Alternatively, use the label facet to define the menu title. If the label facet is used, the label attribute is not necessary.

13.1.2. Menu content

To set the content of the drop-down menu and any sub-menus, use the <rich:menuItem>, <rich:menuGroup>, and <rich:menuSeparator> components. These components are detailed in Section 13.2, “Menu sub-components”.

13.1.3. Appearance

Use the jointPoint and direction attributes to determine the direction and location of the menu when it appears. The jointPoint and direction attributes both use the following settings:
When used with the `jointPoint` attribute, the menu is attached to the top-left, top-right, bottom-left, or bottom-right of the control as appropriate.

When used with the `direction` attribute, the menu appears to the top-left, top-right, bottom-left, or bottom-right of the joint location as appropriate.

The direction or joint location is determined automatically.

When used with the `jointPoint` attribute, the joint location is determined automatically, but defaults to either the left, right, top, or bottom of the control as appropriate.

When used with the `direction` attribute, the menu direction is determined automatically, but defaults to either the left, right, top, or bottom of the joint location as appropriate.

**13.1.4. Expanding and collapsing the menu**

By default, the menu drops down when the title is clicked. To drop down with a different event, use the `eventShow` attribute to define the event instead.

Menus can be navigated using the keyboard. Additionally, menus can be navigated programmatically using the JavaScript API. The JavaScript API allows the following methods:

- `show()`  
  The `show()` method shows the menu.
- `hide()`  
  The `hide()` method hides the menu.
- `activateItem(menuItemId)`  
  The `activateItem(menuItemId)` activates the menu item with the `menuItemId` identifier.

Use the `mode` attribute to determine how the menu requests are submitted:

- `server`, the default setting, submits the form normally and completely refreshes the page.
- `ajax` performs an Ajax form submission, and re-renders elements specified with the `render` attribute.
- `client` causes the `action` and `actionListener` items to be ignored, and the behavior is fully defined by the nested components or custom JavaScript instead of responses from submissions.

**13.1.5. Reference data**

- `component-type: org.richfaces.DropDownMenu`
• component-class: org.richfaces.component.html.HtmlDropDownMenu
• component-family: org.richfaces.DropDownMenu
• renderer-type: org.richfaces.DropDownMenuRenderer
• tag-class: org.richfaces.taglib.DropDownMenuTag

13.2. Menu sub-components

The <rich:menuItem>, <rich:menuGroup>, and <rich:menuSeparator> components are used to construct menus for the <rich:dropDownMenu> component. Refer to Section 13.1, "<rich:dropDownMenu>" for more details on the <rich:dropDownMenu> component.

13.2.1. <rich:menuItem>

The <rich:menuItem> component represents a single item in a menu control. The <rich:menuItem> component can be also be used as a separate component without a parent menu component, such as on a toolbar.

13.2.1.1. Basic usage

The <rich:menuItem> component requires the label attribute for basic usage. The label attribute is the text label for the menu item.

13.2.1.2. Appearance

Icons can be added to menu items through the use of two icon attributes. The icon attribute specifies the normal icon, while the iconDisabled attribute specifies the icon for a disabled item.

Alternatively, define facets with the names icon and iconDisabled to set the icons. If facets are defined, the icon and iconDisabled attributes are ignored. Using facets for icons allows more complex usage; example shows a checkbox being used in place of an icon.

Example 13.1. Icon facets

```xml
<rich:menuItem value="Show comments">
  <f:facet name="icon">
    <h:selectBooleanCheckbox value="#{bean.property}"/>
  </f:facet>
</rich:menuItem>
```

13.2.1.3. Submission modes

Use the submitMode attribute to determine how the menu item requests are submitted:

• server, the default setting, submits the form normally and completely refreshes the page.
ajax performs an Ajax form submission, and re-renders elements specified with the render attribute.

client causes the action and actionListener items to be ignored, and the behavior is fully defined by the nested components instead of responses from submissions.

13.2.1.4. Reference data

- component-type: org.richfaces.MenuItem
- component-class: org.richfaces.component.html.HtmlMenuItem
- component-family: org.richfaces.DropDownMenu
- renderer-type: org.richfaces.MenuItemRenderer
- tag-class: org.richfaces.taglib.MenuItemTag

13.2.2. <rich:menuGroup>

The <rich:menuGroup> component represents an expandable sub-menu in a menu control. The <rich:menuGroup> component can contain a number of <rich:menuItem> components, or further nested <rich:menuGroup> components.

13.2.2.1. Basic usage

The <rich:menuGroup> component requires the value attribute for basic usage. The value attribute is the text label for the menu item.

Additionally, the <rich:menuGroup> component must contain child <rich:menuItem> components or <rich:menuGroup> components.

13.2.2.2. Appearance

Icons can be added to menu groups through the use of two icon attributes. The icon attribute specifies the normal icon, while the iconDisabled attribute specifies the icon for a disabled group.

Alternatively, define facets with the names icon and iconDisabled to set the icons. If facets are defined, the icon and iconDisabled attributes are ignored.

The <rich:menuGroup> component can be positioned using the jointPoint and direction attributes, the same as the parent menu control. For details on the jointPoint and direction attributes, refer to Section 13.1.3, “Appearance”.

13.2.2.3. Reference data

- component-type: org.richfaces.MenuGroup
- component-class: org.richfaces.component.html.HtmlMenuGroup
13.2.3. `<rich:menuSeparator>`

The `<rich:menuSeparator>` component represents a separating divider in a menu control.

13.2.3.1. Basic usage

The `<rich:menuSeparator>` component does not require any attributes for basic usage. Add it as a child to a menu component to separator menu items and menu groups.

13.2.3.2. Reference data

```
• component-type: org.richfaces.MenuSeparator
• component-class: org.richfaces.component.html.HtmlMenuSeparator
• component-family: org.richfaces.DropDownMenu
• renderer-type: org.richfaces.MenuSeparatorRenderer
• tag-class: org.richfaces.taglib.MenuSeparatorTag
```

13.3. `<rich:panelMenu>`

The `<rich:panelMenu>` component is used in conjunction with `<rich:panelMenuItem>` and `<rich:panelMenuGroup>` to create an expanding, hierarchical menu. The `<rich:panelMenu>` component's appearance can be highly customized, and the hierarchy can stretch to any number of sub-levels.

**Example 13.2. richpanelMenu**

```
<rich:panelMenu mode="ajax"
    topGroupExpandedRightIcon="chevronUp"
    topGroupCollapsedRightIcon="chevronDown"
    groupExpandedLeftIcon="disc"
    groupCollapsedLeftIcon="disc">
    <rich:panelMenuGroup label="Group 1">
        <rich:panelMenuItem label="Item 1.1"/>
        <rich:panelMenuItem label="Item 1.2"/>
        <rich:panelMenuItem label="Item 1.3"/>
    </rich:panelMenuGroup>
    <rich:panelMenuGroup label="Group 2">
        <rich:panelMenuItem label="Item 2.1"/>
        <rich:panelMenuItem label="Item 2.2"/>
    </rich:panelMenuGroup>
</rich:panelMenu>
```
13.3.1. Basic usage

The `<rich:panelMenu>` component does not need any extra attributes declared for basic usage. However, it does require child `<rich:panelMenuGroup>` and `<rich:panelMenuItem>` components. Refer to Section 13.3.6, “<rich:panelMenuGroup>” and Section 13.3.7, “<rich:panelMenuItem>” for details on these child components.

13.3.2. Interactivity options

The `activeItem` attribute is used to point to the name of the currently selected menu item.

By default, the event to expand the menu is a mouse click. Set the `expandEvent` attribute to specify a different event to expand menus. Multiple levels of sub-menus can be expanded in one action. Set `expandSingle="true"` to only expand one sub-menu at a time.

Similarly, the default event to collapse the menu is a mouse click. Set the `collapseEvent` attribute to specify a different event to collapse menus.

As with other control components, set `disabled="true"` to disable the `<rich:panelMenu>` component. Child menu components can be disabled in the same way.
13.3.3. Appearance

Icons for the panel menu can be chosen from a set of standard icons. Icons can be set for the top panel menu, child panel menus, and child item. There are three different menu states that the icon represents, as well as icons for both the left and right side of the item title. The icons can also be managed using facets.

- `topGroupExpandedLeftIcon`, `topGroupExpandedRightIcon`
  These attributes determine the icons for the top level menu when it is expanded. The related facet is the `topGroupExpandedClass` facet.

- `topGroupCollapsedLeftIcon`, `topGroupCollapsedRightIcon`
  These attributes determine the icons for the top level menu when it is collapsed. The related facet is the `topGroupCollapsedClass` facet.

- `topGroupDisabledLeftIcon`, `topGroupDisabledRightIcon`
  These attributes determine the icons for the top level menu when it is disabled. The related facet is the `topGroupDisabledClass` facet.

- `topItemLeftIcon`, `topItemRightIcon`
  These attributes determine the icons for a top level menu item. The related facet is the `topItemClass` facet.

- `topItemDisabledLeftIcon`, `topItemDisabledRightIcon`
  These attributes determine the icons for a top level menu item when it is disabled. The related facet is the `topItemDisabledClass` facet.

- `groupExpandedLeftIcon`, `groupExpandedRightIcon`
  These attributes determine the icons for sub-menus that are not the top-level menu when they are expanded. The related facet is the `groupExpandedClass` facet.

- `groupCollapsedLeftIcon`, `groupCollapsedRightIcon`
  These attributes determine the icons for sub-menus that are not the top-level menu when they are collapsed. The related facet is the `groupCollapsedClass` facet.

- `groupDisabledLeftIcon`, `groupDisabledRightIcon`
  These attributes determine the icons for sub-menus that are not the top-level menu when they are disabled. The related facet is the `groupDisabledClass` facet.

- `itemLeftIcon`, `itemRightIcon`
  These attributes determine the icons for items in the menus. The related facet is the `itemClass` facet.

- `itemDisabledLeftIcon`, `itemDisabledRightIcon`
  These attributes determine the icons for items in the menus when they are disabled. The related facet is the `itemDisabledClass` facet.

*Example 13.2, "richpanelMenu"* demonstrates the use of icon declaration at the panel menu level. The standard icons are shown in *Figure 13.2, "<Standard icons>"*. 

Alternatively, point the icon attributes to the paths of image files. The image files are then used as icons.

Any icons specified by child <rich:panelMenuGroup> and <rich:panelMenuItem> components overwrite the relevant icons declared with the parent <rich:panelMenu> component.

### 13.3.4. Submission modes

The `itemMode` attribute defines the submission mode for normal menu items that link to content, and the `groupMode` attribute defines the submission mode for menu items that expand and collapse. The settings for these attributes apply to the entire menu unless a menu item defines its own individual `itemMode` or `groupMode`. The possible values for `itemMode` and `groupMode` are as follows:

- **server**, the default setting, which submits the form normally and completely refreshes the page.
- **ajax**, which performs an Ajax form submission, and re-renders elements specified with the `render` attribute.
- **none**, which causes the `action` and `actionListener` items to be ignored, and the behavior is fully defined by the nested components instead of responses from submissions.

### 13.3.5. Reference data

- `component-type`: org.richfaces.PanelMenu
- `component-class`: org.richfaces.component.html.HtmlPanelMenu
- `component-family`: org.richfaces.PanelMenu
- `renderer-type`: org.richfaces.PanelMenuRenderer
- `tag-class`: org.richfaces.taglib.PanelMenuTag

### 13.3.6. <rich:panelMenuGroup>

The `<rich:panelMenuGroup>` component defines a group of `<rich:panelMenuItem>` components inside a `<rich:panelMenu>`. 
13.3.6.1. Basic usage

The `<rich:panelMenuGroup>` component needs the `label` attribute declared, which specifies the text to show for the menu entry. Additionally, the `<rich:panelMenuGroup>` component at least one `<rich:panelMenuGroup>` or `<rich:panelMenuItem>` components as child elements.

13.3.6.2. Appearance

Icons for the menu group are inherited from the parent `<rich:panelMenu>` component. Refer to Section 13.3.3, “Appearance” for details on icon attributes and facets. Alternatively, the menu group's icons can be re-defined at the `<rich:panelMenuGroup>` component level, and these settings will be used instead of the parent component's settings.

13.3.6.3. Submission modes

If the `mode` attribute is unspecified, the submission behavior for the group is inherited from the parent `<rich:panelMenu>`. Otherwise, the `mode` setting is used instead of the parent's behavior. Refer to Section 13.3.4, “Submission modes” for submission mode settings.

13.3.6.4. Reference data

- `component-type`: `org.richfaces.PanelMenuGroup`
- `component-class`: `org.richfaces.component.html.HtmlPanelMenuGroup`
- `component-family`: `org.richfaces.PanelMenuGroup`
- `renderer-type`: `org.richfaces.PanelMenuGroupRenderer`
- `tag-class`: `org.richfaces.taglib.PanelMenuGroupTag`

13.3.7. `<rich:panelMenuItem>`

The `<rich:panelMenuItem>` component represents a single item inside a `<rich:panelMenuGroup>` component, which is in turn part of a `<rich:panelMenu>` component.

13.3.7.1. Basic usage

The `<rich:panelMenuItem>` component needs the `label` attribute declared, which specifies the text to show for the menu entry.

13.3.7.2. Appearance

Icons for the menu item are inherited from the parent `<rich:panelMenu>` or `<rich:panelMenuGroup>` component. Refer to Section 13.3.3, “Appearance” for details on icon attributes and facets. Alternatively, the menu item's icons can be re-defined at the `<rich:panelMenuItem>` component level, and these settings will be used instead of the parent component's settings.
13.3.7.3. Submission modes

If the mode is unspecified, the submission behavior for the item is inherited from the parent <rich:panelMenu>. Otherwise, the mode setting is used instead of the parent's behavior.

13.3.7.4. Reference data

- **component-type**: org.richfaces.PanelMenuItem
- **component-class**: org.richfaces.component.html.HtmlPanelMenuItem
- **component-family**: org.richfaces.PanelMenuItem
- **renderer-type**: org.richfaces.PanelMenuItemRenderer
- **tag-class**: org.richfaces.taglib.PanelMenuItemTag

13.4. <rich:toolbar>

The <rich:toolbar> component is a horizontal toolbar. Any JavaServer Faces (JSF) component can be added to the toolbar.

### Figure 13.3. <rich:toolbar>

13.4.1. Basic usage

The <rich:toolbar> component does not require any attributes to be defined for basic usage. Add child components to the <rich:toolbar> component to have them appear on the toolbar when rendered.

**Example 13.3. Basic usage**

```xml
<rich:toolbar>
    <h:commandLink value="News" />
    <h:commandLink value="Reviews" />
    <h:commandLink value="Galleries" />
</rich:toolbar>
```

13.4.2. Appearance

Set the width and height of the toolbar using the common width and height attributes.

Items on the toolbar can be separated by a graphical item separator. Use the itemSeparator attribute to specify one of the standard separator styles:
13.4.3. Grouping items

Group together multiple items on the toolbar by using the <rich:toolbarGroup> child component. Refer to Section 13.4.5, “<rich:toolbarGroup>” for full details on the <rich:toolbarGroup> component.

13.4.4. Reference data

- component-type: org.richfaces.Toolbar
- component-class: org.richfaces.component.html.HtmlToolbar
- component-family: org.richfaces.Toolbar
- renderer-type: org.richfaces.ToolbarRenderer
- tag-class: org.richfaces.taglib.ToolbarTag

13.4.5. <rich:toolbarGroup>

The <rich:toolbarGroup> component is a child component of the <rich:toolbar> component. The <rich:toolbarGroup> component is used to group a number of items together on a toolbar.

13.4.5.1. Basic usage

Like the <rich:toolbar> parent component, the <rich:toolbarGroup> component does not require any extra attributes for basic functionality. Add child components to the
13.4.5.2. Appearance

Similar to the `<rich:toolbar>` component, items within a `<rich:toolbarGroup>` can be separated by specifying the `itemSeparator` attribute. Refer to Section 13.4.2, “Appearance” for details on using the `itemSeparator` attribute.

Groups of toolbar items can be located on either the left-hand side or the right-hand side of the parent toolbar. By default, they appear to the left. To locate the toolbar group to the right of the parent toolbar, set `location="right"`.

Example 13.4. `<rich:toolbarGroup>`

```xml
<rich:toolbar height="26" itemSeparator="grid">
    <rich:toolbarGroup>
        <h:graphicImage value="/images/icons/create_doc.gif"/>
        <h:graphicImage value="/images/icons/create_folder.gif"/>
        <h:graphicImage value="/images/icons/copy.gif"/>
    </rich:toolbarGroup>
    <rich:toolbarGroup>
        <h:graphicImage value="/images/icons/save.gif"/>
        <h:graphicImage value="/images/icons/save_as.gif"/>
        <h:graphicImage value="/images/icons/save_all.gif"/>
    </rich:toolbarGroup>
    <rich:toolbarGroup location="right">
        <h:graphicImage value="/images/icons/find.gif"/>
        <h:graphicImage value="/images/icons/filter.gif"/>
    </rich:toolbarGroup>
</rich:toolbar>
```

The example shows how to locate a toolbar group to the right-hand side of the parent toolbar. It also demonstrates how item separators on the parent toolbar work with toolbar groups.

13.4.5.3. Reference data

- `component-type`: `org.richfaces.ToolbarGroup`
- `component-class`: `org.richfaces.component.html.HtmlToolbarGroup`
- `component-family`: `org.richfaces.ToolbarGroup`
- `renderer-type`: `org.richfaces.ToolbarGroupRenderer`
• tag-class: org.richfaces.taglib.ToolbarGroupTag
Output and messages

14.1. <rich:message>

The <rich:message> component renders a single message relating to another specific component. The message consists of two parts, both of which are optional: the marker icon and the textual label. The appearance of the message can be customized, and tool-tips can be used for further information about the message.

**Figure 14.1. rich:message component**

14.1.1. Basic usage

The <rich:message> component needs the for attribute to point to the id identifier of the related component. The message is displayed depending on the state of the linked component's requests.

The <rich:message> component is automatically rendered after an Ajax request, even without the use of an <a4j:outputPanel> component.

14.1.2. Appearance

The passedLabel attribute contains a message to display when there are no errors; that is, when validation passes successfully. The showSummary attribute specifies whether to display only a summary of the full message. The full message can be displayed in a tool-tip when hovering the mouse over the summary.

Facets are used to define the marker icons for different message states:

- **errorMarker**
  
  Defines the icon for messages with the error severity class.
Chapter 14. Output and messages

fatalMarker
Defines the icon for messages with the fatal severity class.

infoMarker
Defines the icon for messages with the info severity class.

passedMarker
Defines the icon for messages that are not of the error, fatal, info, or warn severity classes.

warnMarker
Defines the icon for messages with the warn severity class.

Example 14.1. rich:message example

```xml
<rich:message
  for="id" passedLabel="No errors" showSummary="true">
  <f:facet name="errorMarker">
    <h:graphicImage url="/image/error.png"/>
  </f:facet>
  <f:facet name="passedMarker">
    <h:graphicImage url="/image/passed.png"/>
  </f:facet>
</rich:message>
```

14.1.3. Reference data

- component-type: org.richfaces.component.RichMessage
- component-family: org.richfaces.component.RichMessage
- renderer-type: org.richfaces.RichMessageRenderer
- tag-class: org.richfaces.taglib.RichMessageTag

14.2. <rich:messages>

The <rich:messages> component works similarly to the <rich:message> component, but can display validation messages for a group of components instead of just a single component. Refer to Section 14.1, “<rich:message>” for details on the <rich:message> component.

Figure 14.2. rich:messages component
14.2.1. Basic usage

The `<rich:messages>` component doesn't require any extra attributes for basic usage. It displays all messages relating to requests from components in the same container element.

The `<rich:message>` component is automatically rendered after an Ajax request, even without the use of an `<a4j:outputPanel>` component.

14.2.2. Appearance

The `<rich:messages>` component displays error messages for each validating component in the same container. The `passLabel` attribute contains a message to display when there are no errors; that is, when validation for all components passes successfully. The `layout` attribute defines how the messages are presented: either using `list` for a list layout, or `table` for a tabular layout.

All messages use the same state icons, specified by using facets in the same way as for the `<rich:message>` component:

`errorMarker`
- Defines the icon for messages with the `error` severity class.

`fatalMarker`
- Defines the icon for messages with the `fatal` severity class.

`infoMarker`
- Defines the icon for messages with the `info` severity class.

`passedMarker`
- Defines the icon for messages that are not of the `error`, `fatal`, `info`, or `warn` severity classes.

`warnMarker`
- Defines the icon for messages with the `warn` severity class.

Example 14.2. rich:messages example

```xml
<h:form>
    <rich:messages passedLabel="Data validated." layout="list">
        <f:facet name="header">
            <h:outputText value="Entered Data Status:"></h:outputText>
        </f:facet>
        <f:facet name="passedMarker">
            <h:graphicImage value="/images/ajax/passed.gif" />
        </f:facet>
        <f:facet name="errorMarker">
            <h:graphicImage value="/images/ajax/error.gif" />
        </f:facet>
    </rich:messages>
</h:form>
```
### 14.2.3. Reference data

- **component-type**: org.richfaces.component.RichMessages
- **component-class**: org.richfaces.component.html.HtmlRichMessages
- **component-family**: org.richfaces.component.RichMessages
- **renderer-type**: org.richfaces.RichMessagesRenderer
- **tag-class**: org.richfaces.taglib.RichMessagesTag

### 14.3. `<rich:progressBar>`

The `<rich:progressBar>` component displays a progress bar to indicate the status of a process to the user. It can update either through Ajax or on the client side, and the look and feel can be fully customized.

![Example progress bar at 50%](50%)

**Figure 14.3. `<rich:progressBar>`**
14.3.1. Basic usage

Basic usage of the `<rich:progressBar>` component requires only the `value` attribute, which points to the method that provides the current progress.

**Example 14.3. Basic usage**

```xml
<rich:progressBar value="#{bean.incValue}" />
```

14.3.2. Customizing the appearance

By default, the minimum value of the progress bar is 0 and the maximum value of the progress bar is 100. These values can be customized using the `minValue` and `maxValue` attributes respectively.

The progress bar can be labeled in one of two ways:

Using the `label` attribute

The content of the `label` attribute is displayed over the progress bar.

**Example 14.4. Using the `label` attribute**

```xml
<rich:progressBar value="#{bean.incValue}" id="progrsLabel="#{bean.incValue}"/>
```

Using nested child components

Child components, such as the JSF `<h:outputText>` component, can be nested in the `<rich:progressBar>` component to display over the progress bar.

**Example 14.5. Using nested child components**

```xml
<rich:progressBar value="#{bean.incValue}"
  <h:outputText value="#{bean.incValue} %"/>
</rich:progressBar>
```

Macro-substitution

The following section details the use of macro-substitution parameters in labeling. Macro-substitution may be revised and altered in future versions of RichFaces. Be aware of this when using macro-substitution in your applications.
For labeling, the `<rich:progressBar>` component recognizes three macro-substitution parameters:

- `{value}`
  - The current progress value.
- `{minValue}`
  - The minimum value for the progress bar.
- `{maxValue}`
  - The maximum value for the progress bar.

**Example 14.6. Using macro-substitution for labeling**

```xml
<rich:progressBar value="#{bean.incValue1}" minValue="400" maxValue="900">
  <h:outputText value="Minimum value is {minValue}, current value is {value}, maximum value is {maxValue}"/>
</rich:progressBar>
```

Additionally, you can use the `{param}` parameter to specify any custom parameters you require. Define the parameters in the bean for the progress method, then reference it with the `<rich:progressBar>` component's `parameters` attribute, as shown in Example 14.7, “Using the `param` parameter”.

**Example 14.7. Using the `param` parameter**

```xml
<rich:progressBar value="#{bean.incValue}" parameters="param:'#{bean.dwnlSpeed}'">
  <h:outputText value="download speed {param} KB/s"/>
</rich:progressBar>
```

To define customized initial and complete states for the progress bar, use the `initial` and `complete` facets. The `initial` facet displays when the progress value is less than or equal to the minimum value, and the `complete` facet displays when the progress value is greater than or equal to the maximum value.

**Example 14.8. Initial and complete states**

```xml
<rich:progressBar value="#{bean.incValue1}"

  <f:facet name="initial">
    <h:outputText value="Process not started"/>
  </f:facet>

  <f:facet name="complete">
    <h:outputText value="Process completed"/>
  </f:facet>

</rich:progressBar>
```
14.3.3. Using set intervals

The `<rich:progressBar>` component can be set to constantly poll for updates at a constant interval. Use the `interval` component to set the interval in milliseconds. The progress bar is updated whenever the polled value changes. Polling is only active when the `enabled` attribute is set to `true`.

Example 14.9. Using set intervals

```html
<rich:progressBar
    value="#{bean.incValue1}"
    id="progress"
    interval="900"
    enabled="#{bean.enabled1}"
/>
```

14.3.4. Update mode

The mode for updating the progress bar is determined by the `mode` attribute, which can have one of the following values:

- `ajax`
  The progress bar updates in the same way as the `<a4j:poll>` component. The `<rich:progressBar>` component repeatedly polls the server for the current progress value.

- `client`
  The progress bar updates on the client side, set using the JavaScript API.

14.3.5. Reference data

- `component-type`: `org.richfaces.ProgressBar`
- `component-class`: `org.richfaces.component.html.HtmlProgressBar`
- `component-family`: `org.richfaces.component.ProgressBar`
- `renderer-type`: `org.richfaces.renderkit.ProgressBarRenderer`
- `tag-class`: `org.richfaces.taglib.ProgressBarTag`

14.4. `<rich:toolTip>`

The `<rich:toolTip>` component provides an informational tool-tip. The tool-tip can be attached to any control and is displayed when hovering the mouse cursor over the control.
14.4.1. Basic usage

For basic usage, define the tool-tip text using the value attribute. The <rich:toolTip> component is then automatically attached to the parent element, and is usually shown when the mouse cursor hovers.

Alternatively, the content of the tool-tip can be defined inside the <rich:toolTip> tags, and the value attribute is not used. This allows HTML tags to be used to define the content, and provides for rich content such as images, links, buttons, and other RichFaces components.

**Example 14.10. Defining tool-tip content**

Basic content

```xml
<rich:panel>
  <rich:toolTip value="This is a tool-tip."
</rich:panel>
```

Rich content

```xml
<rich:panel>
  <rich:toolTip>
    This is a <b>tool-tip</b>.
  </rich:toolTip>
</rich:panel>
```

14.4.2. Attaching the tool-tip to another component

If not otherwise specified, the tool-tip is attached to the parent element in which it is defined. The for attribute is used to attach the tool-tip to another component, pointing to the target component's id identifier. This allows the <rich:toolTip> component to be specified outside the target element. This approach is demonstrated in Example 14.11, “Attaching the tool-tip”.

**Example 14.11. Attaching the tool-tip**

```xml
<rich:panel id="panelId">
```
The `<rich:toolTip>` component can alternatively be left unattached, and is instead invoked through an event handler on the target component. To leave the `<rich:toolTip>` component unattached, set `attached="false"`, and define the event handler to trigger the tool-tip on the target component. This approach is demonstrated in Example 14.12, “Unattached tool-tips”. When leaving the `<rich:toolTip>` component unattached, ensure it has an id identifier defined. If the `<rich:toolTip>` component is nested inside the target element, it must be the last child. If it is defined outside the target element, it must be nested in an `<a4j:form>` component.

**Example 14.12. Unattached tool-tips**

```html
<rich:panel id="panelId" onclick="#{rich:component("tooltipId")}.show(event);" />
<a4j:form>
    <rich:toolTip id="toolTipId" attached="false" value="This is a tool-tip."/>
</a4j:form>
```

### 14.4.3. Appearance

By default, the `<rich:toolTip>` component is positioned intelligently based on the position of the mouse cursor. Use the `direction` attribute to specify a corner of the target component at which to display the tool-tip instead. Possible values include `top-left`, `top-right`, `bottom-left`, and `bottom-right`. Use the `horizontalOffset` and `verticalOffset` attributes to specify the horizontal offset and vertical offset at which to display the tool-tip.

Use the `hideEvent` attribute to specify when the tool-tip is hidden. The default value is `none`, so the tool-tip remains shown. However, it can be linked to an event on the target component, such as the `mouseout` event.

Set `followMouse="true"` to cause the tool-tip to follow the user’s mouse movements.

Advanced appearance features are demonstrated in Example 14.13, “Advanced tool-tip usage”.

### 14.4.4. Update mode

The mode for updating the tool-tip is determined by the `mode` attribute, which can have one of the following values:

- `ajax`
  - The tool-tip content is requested from the server with every activation.
The tool-tip content is rendered once on the server. An external submit causes the content to re-render.

When using `mode="ajax"`, define the `defaultContent` facet. The tool-tip displays the content of the `defaultContent` facet while loading the actual content from the server.

**Example 14.13. Advanced tool-tip usage**

```xml
<h:commandLink value="Simple Link" id="link">
    <rich:toolTip followMouse="true" direction="top-right" mode="ajax" value="#{bean.toolTipContent}"
        horizontalOffset="5" verticalOffset="5" layout="block">
        <f:facet name="defaultContent">
            <f:verbatim>Loading...</f:verbatim>
        </f:facet>
    </rich:toolTip>
</h:commandLink>
```

### 14.4.5. `<rich:toolTip>` client-side events

The `<rich:toolTip>` component supports the following client-side events:

- **click**
  This event is activated when the tool-tip is clicked with the mouse.

- **dblclick**
  This event is activated when the tool-tip is double-clicked with the mouse.

- **mouseout**
  This event is activated when the mouse cursor leaves the tool-tip.

- **mousemove**
  This event is activated when the mouse cursor moves over the tool-tip.

- **mouseover**
  This event is activated when the mouse cursor hovers over the tool-tip.

- **show**
  This event is activated when the tool-tip is shown.

- **complete**
  This event is activated when the tool-tip is completed.

- **hide**
  This event is activated when the tool-tip is hidden.

- tag-class: org.richfaces.taglib.HtmlToolTipTag
Chapter 15.

Drag and drop

**Documentation in development**

Some concepts covered in this chapter may refer to the previous version of Richfaces, version 3.3.3. This chapter is scheduled for review to ensure all information is up to date.

Read this chapter for details on adding drag and drop support to controls.

15.1. `<rich:dragSource>`

The `<rich:dragSource>` behavior can be added to a component to indicate it is capable of being dragged by the user. The dragged item can then be dropped into a compatible drop area, designated using the `<rich:dropTarget>` behavior.

15.1.1. Basic usage

To add drag support to a component, attach the `<rich:dragSource>` behavior as a child element. The `type` attribute must be specified, and can be any identifying string. Dragged items can only be dropped in drop zones where the `type` attribute of the `<rich:dragSource>` behavior is listed in the `acceptedTypes` attribute of the `<rich:dropTarget>` behavior.

15.1.2. Dragging an object

Use the `dragIndicator` parameter to customize the appearance of a dragged object while it is being dragged. The `dragIndicator` parameter must point to the `id` identifier of a `<rich:dragIndicator>` component.

To bind data to the dragged object, use the `dragValue` attribute. The `dragValue` attribute specifies an item in a data model, which is then bound to the parent component when it is dragged. This facilitates handling event data during a drop event.

15.1.3. Reference data

- `component-type`: org.richfaces.DragSource
- `component-class`: org.richfaces.component.html.HtmlDragSource
- `component-family`: org.richfaces.DragSource
- `renderer-type`: org.richfaces.DragSourceRenderer
- `tag-class`: org.richfaces.taglib.DragSourceTag
15.2. `<rich:dropTarget>`

The `<rich:dropTarget>` behavior can be added to a component so that the component can accept dragged items. The dragged items must support the `<rich:dragSource>` behavior, and be of a compatible drop type.

### 15.2.1. Basic usage

To allow dragged items to be dropped on a component, attach the `<rich:dropTarget>` behavior as a child element to the component.

The `acceptedTypes` attribute must be specified. The `acceptedTypes` attribute is a comma-separated list of strings that match the types of dragged items. Dragged items can only be dropped in drop zones where the `type` attribute of the `<rich:dragSource>` behavior is listed in the `acceptedTypes` attribute of the `<rich:dropTarget>` behavior.

The `acceptedTypes` attribute can optionally be set to either `@none` or `@all`. If set to `@none`, the component will not accept any type of dropped object. If set to `@all`, the component accepts all dropped objects. If the `acceptedTypes` attribute is not specified, the default value is `null`, which is the same as a `@none` setting.

### 15.2.2. Handling dropped data

To provide additional parameters for a drop event, use the `dropValue` attribute.

The `<rich:dropTarget>` behavior raises the `DropEvent` server-side event when an object is dropped. The event uses the following parameters:

- The `dragSource` identifies the component being dragged (the parent of the `<rich:dragSource>` behavior).
- The `dragValue` parameter is the content of the `<rich:dragSource>` behavior's `dragValue` attribute.
- The `dropValue` parameter is the content of the `<rich:dropTarget>` behavior's `dropValue` attribute.

### 15.2.3. Reference data

- `component-type: org.richfaces.DropTarget`
- `component-class: org.richfaces.component.html.HtmlDropTarget`
- `component-family: org.richfaces.DropTarget`
- `renderer-type: org.richfaces.DropTargetRenderer`
- `tag-class: org.richfaces.taglib.DropTargetTag`
15.3. `<rich:dragIndicator>`

The `<rich:dragIndicator>` component defines a graphical element to display under the mouse cursor during a drag-and-drop operation.

### 15.3.1. Basic usage

If included without any attributes specified, the drag indicator will appear as an empty dotted outline, as shown in

![Figure 15.1. An empty drag indicator](image)

### 15.3.2. Styling the indicator

The drag indicator can be styled depending on the current state of the dragged element. There are three attributes for different states. The attributes reference the CSS class to use for styling the drag indicator when the dragged element is in the relevant state.

- **acceptClass**
  
  The `acceptClass` attribute specifies the style when the dragged element is over an acceptable drop target. It indicates that the `type` attribute of the element's `<rich:dragSource>` behavior matches the `acceptedTypes` attribute of the drop target's `<rich:dropTarget>` behavior.

- **rejectClass**
  
  The `rejectClass` attribute specifies the style when the dragged element is over a drop target that is not acceptable. It indicates that the `type` attribute of the element's `<rich:dragSource>` behavior is not found in the `acceptedTypes` attribute of the drop target's `<rich:dropTarget>` behavior.

- **draggingClass**
  
  The `draggingClass` attribute specifies the style when the dragged element is being dragged. It indicates that the dragged element is not over a drop target.

### 15.3.3. Reference data

- `component-type: org.richfaces.DragIndicator`
- `component-class: org.richfaces.component.html.HtmlDragIndicator`
• `component-family': `org.richfaces.DragIndicator`

• `renderer-type': `org.richfaces.DragIndicatorRenderer`

• `tag-class': `org.richfaces.taglib.DragIndicatorTag`
Layout and appearance

Documentation in development

Some concepts covered in this chapter may refer to the previous version of Richfaces, version 3.3.3. This chapter is scheduled for review to ensure all information is up to date.

Read this chapter to alter the layout and appearance of web applications using special components.

16.1. <rich:jQuery>

The <rich:jQuery> component applies styles and custom behavior to both JSF (JavaServer Faces) objects and regular DOM (Document Object Model) objects. It uses the jQuery JavaScript framework to add functionality to web applications.

16.1.1. Basic usage

The query triggered by the <rich:jQuery> component is specified using the query attribute.

With the query defined, the component is used to trigger the query as either a timed query or a named query. The query can be bound to an event to act as an event handler. These different approaches are covered in the following sections.

16.1.2. Defining a selector

Any objects or lists of objects used in the query are specified using the selector attribute. The selector attribute references objects using the following method:

- The selector attribute can refer to the id identifier of any JSF component or client.
- If the selector attribute does not match the id identifier attribute of any JSF components or clients on the page, it instead uses syntax defined by the World Wide Web Consortium (W3C) for the CSS rule selector. Refer to the syntax specification at http://api.jquery.com/category/selectors/ for full details.

Because the selector attribute can be either an id identifier attribute or CSS selector syntax, conflicting values could arise. Example 16.1, “Avoiding syntax confusion” demonstrates how to use double backslashes to escape colon characters in id identifier values.

Example 16.1. Avoiding syntax confusion

```
<h:form id="form">
```
16.1.3. Event handlers

Queries set as event handlers are triggered when the component specified in the selector attribute raises an event. The query is bound to the event defined using the event attribute.

Use the attachType attribute to specify how the event-handling queries are attached to the events:

- **bind**
  - This is the default for attaching queries to events. The event handler is bound to all elements currently defined by the selector attribute.

- **live**
  - The event handler is bound to all current and future elements defined by the selector attribute.

- **one**
  - The event handler is bound to all elements currently defined by the selector attribute. After the first invocation of the event, the event handler is unbound such that it no longer fires when the event is raised.

16.1.4. Timed queries

Timed queries are triggered at specified times. This can be useful for calling simple methods when a page is rendered, or for adding specific functionality to an element. Use the timing attribute to specify the point at which the timed query is triggered:

- **domready**
  - This is the default behavior. The query is triggered when the document is loaded and the DOM is ready. The query is called as a jQuery() function.

- **immediate**
  - The query is triggered immediately. The query is called as an in-line script.
Example 16.2. `<rich:jQuery>` example

```html
<rich:dataTable id="customList" ... >
...
</rich:dataTable>

<rich:jQuery
  selector="#customList
  tr:odd" timing="domready" query="addClass(odd)" />
```

In the example, the selector picks out the odd `<tr>` elements that are children of the element with an `id="customlist"` attribute. The query `addClass(odd)` is then performed on the selection during page loading (load) such that the odd CSS class is added to the selected elements.

<table>
<thead>
<tr>
<th>Make</th>
<th>Model</th>
<th>Price</th>
<th>Mileage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chevrolet</td>
<td>Corvette</td>
<td>39858</td>
<td>64699.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Corvette</td>
<td>38091</td>
<td>38014.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Corvette</td>
<td>18427</td>
<td>64568.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Corvette</td>
<td>35277</td>

<td>73266.0</td>
</tr>
<tr>
<td>Chevrolet</td>
<td>Malibu</td>
<td>41762</td>
<td>18542.0</td>
</tr>
</tbody>
</table>

16.1.5. Named queries

Named queries are given a name such that they can be triggered by other functions or handlers. Use the `name` attribute to name the query. The query can then be accessed as though it were a JavaScript function using the specified `name` attribute as the function name.

Calls to the function must pass a direct reference (`this`) to the calling object as a parameter. This is treated the same as an item defined through the `selector` attribute.

If the function requires extra parameters itself, these are provided in JavaScript Object Notation (JSON) syntax as a second parameter in the JavaScript call. The `options` namespace is then used in the `<rich:jQuery>` query to access the passed function parameters. **Example 16.3, “Calling a `<rich:jQuery>` component as a function”** demonstrates the use of the `name` attribute and how to pass function parameters through the JavaScript calls.

Example 16.3. Calling a `<rich:jQuery>` component as a function

```html
<h:graphicImage
  width="50"
  value="/images/price.png"
  onmouseover="enlargePic(this,pwidth:'60px')"
  onmouseout="releasePic(this)" />
```
Chapter 16. Layout and appearance

The example enlarges the images when the mouse moves over them. The `enlargePic` and `releasePic` components are called like ordinary JavaScript functions from the image elements.

16.1.6. Dynamic rendering

The `<rich:jQuery>` component applies style and behavioral changes to DOM objects dynamically. As such, changes applied during an Ajax response are overwritten, and will need to be re-applied once the Ajax response is complete.

Any timed queries with the `timing` attribute set to `domready` may not update during an Ajax response, as the DOM document is not completely reloaded. To ensure the query is re-applied after an Ajax response, include the `name` attribute in the `<rich:jQuery>` component and invoke it using JavaScript from the `complete` event attribute of the component that triggered the Ajax interaction.

16.1.7. Reference data

- `component-type`: `org.richfaces.JQuery`
- `component-class`: `org.richfaces.component.html.HtmlJQuery`
- `component-family`: `org.richfaces.JQuery`
- `renderer-type`: `org.richfaces.JQueryRenderer`
- `tag-class`: `org.richfaces.taglib.JQueryTag`
Functions

Read this chapter for details on special functions for use with particular components. Using JavaServer Faces Expression Language (JSF EL), these functions can be accessed through the data attribute of components. Refer to Section 2.5.7, “data” for details on the data attribute.

17.1. rich:clientId

The rich:clientId('id') function returns the client identifier related to the passed component identifier ('id'). If the specified component identifier is not found, null is returned instead.

17.2. rich:component

The rich:component('id') function is a shortcut for the equivalent #{rich:clientId('id')}.component code. It returns the UIComponent instance from the client, based on the passed server-side component identifier ('id'). If the specified component identifier is not found, null is returned instead.

17.3. rich:element

The rich:element('id') function is a shortcut for the equivalent document.getElementById(#{rich:clientId('id')}) code. It returns the element from the client, based on the passed server-side component identifier. If the specified component identifier is not found, null is returned instead.

17.4. rich:findComponent

The rich:findComponent('id') function returns the a UIComponent instance of the passed component identifier. If the specified component identifier is not found, null is returned instead.

Example 17.1. rich:findComponent example

```html
<h:inputText id="myInput">
    <a4j:support event="keyup" render="outtext"/>
</h:inputText>
<h:outputText id="outtext" value="#{rich:findComponent('myInput').value}"/>
```

17.5. rich:isUserInRole

The rich:isUserInRole(Object) function checks whether the logged-in user belongs to a certain user role, such as being an administrator. User roles are defined in the web.xml settings file.
Example 17.2. rich:isUserInRole example

The rich:isUserInRole(Object) function can be used in conjunction with the rendered attribute of a component to only display certain controls to authorized users.

```xml
<rich:editor value="#{bean.text}" rendered="#{rich:isUserInRole('admin')}"/>
```
